Franc FORSTNERIČ

On complete intersections

<http://aif.cedram.org/item?id=AIF_2001__51_2_497_0>
1. The results.

In this paper we give examples of closed complex submanifolds in complex euclidean spaces which are differential complete intersections but not holomorphic complete intersections (Theorems 1.1 and 1.2). We also prove a result on removing intersections of holomorphic mappings from Stein manifolds with certain complex subvarieties in euclidean spaces; Theorem 1.3 below extends a result of Forster and Ramspott from 1966 [FRa].

Recall that a closed complex submanifold $Y$ of codimension $d$ in a complex manifold $X$ is a holomorphic complete intersection if there exist $d$ holomorphic functions $f_1, \ldots, f_d \in \mathcal{O}(X)$ such that

$$Y = \{ x \in X : f_1(x) = \ldots = f_d(x) = 0 \}$$

and the differentials $df_j(x)$ ($1 \leq j \leq d$) are $C$-linearly independent at each point $x \in Y$. These differentials induce a trivialization of the complex normal bundle $N_Y = TX|_Y / TY$ of $Y$ in $X$. There is a partial converse when $X$ is a Stein manifold: If the normal bundle $N_Y$ is trivial then $Y$ is a holomorphic complete intersection in some open neighborhood of $Y$ in $X$ (since a neighborhood of $Y$ in $X$ is biholomorphic to a neighborhood of the zero section in the normal bundle $N_Y$; see [GR], p. 256). Similarly, a smooth real submanifold $Y$ of real codimension $d$ in a smooth manifold $X$
is a differential complete intersection if there exist $d$ smooth real functions on $X$ satisfying (1), with independent differentials along $Y$. For results on complete intersections we refer the reader to the papers [Sch] and [BK] and the references therein.

1.1. Theorem. — There exists a three dimensional closed complex submanifold in $\mathbb{C}^5$ which is a differential complete intersection but not a holomorphic complete intersection.

More precisely, given any compact orientable two dimensional surface $M$ of genus $g \geq 2$ we construct a three dimensional Stein manifold $Y$ which is homotopically equivalent to $M$ and whose tangent bundle $TY$ is trivial as a real vector bundle, but is non-trivial as a complex vector bundle. We then show that any proper holomorphic embedding $Y \hookrightarrow \mathbb{C}^5$ (or $Y \hookrightarrow \mathbb{C}^7$) satisfies the conclusion of Theorem 1.1. In fact, we prove

1.2. Theorem. — Let $Y$ be a Stein manifold of dimension $m$ whose tangent bundle is trivial as a real vector bundle, but is non-trivial as a complex vector bundle. Choose integers $m$ and $d$ such that either

(a) $d = 2$ and $m \in \{2, 3\}$, or

(b) $d = 4$ and $2 \leq m \leq 7$.

Then the image of any proper holomorphic embedding $Y \hookrightarrow \mathbb{C}^{m+d}$ is a differential complete intersection but not a holomorphic complete intersection in $\mathbb{C}^{m+d}$.

Multiplying our $Y^3 \subset \mathbb{C}^5$ by $\mathbb{C}^k$ we obtain similar examples in higher dimensions. Submanifolds of this type don’t exist in $\mathbb{C}^n$ for $n \leq 3$, but we don’t know the answer for two dimensional submanifolds in $\mathbb{C}^4$. Recall that every smooth holomorphic curve in $\mathbb{C}^n$ is a holomorphic complete intersection [FRa], and so is every complex hypersurface in $\mathbb{C}^n$ (since all divisors on $\mathbb{C}^n$ are principal).

Example 1. — There exists a Stein manifold $X$ of dimension four and a closed complex submanifold $Y \subset X$ of dimension two such that $Y$ is a differential complete intersection but not a holomorphic complete intersection in $X$. We can choose $Y$ to have the homotopy type of the real two-sphere. (See Proposition 2.4 in Section 2). $\square$

In the remainder of this section we discuss the problem of removing intersections of holomorphic maps from Stein manifolds into $\mathbb{C}^d$ with
certain analytic subvarieties $\Sigma \subset \mathbb{C}^d$. Our main result, Theorem 1.3, contains as a special case the result on complete intersections due to Forster and Ramspott [Fra]. To motivate the discussion we first look at the complete intersections problem in the more general context of complex spaces (with singularities). A closed complex subvariety $Y$ of a complex space $X$ is a holomorphic complete intersection in $X$ if there exist $d = \dim X - \dim Y$ global sections of the analytic sheaf of ideals $\mathcal{J}_Y$ which generate this sheaf at each point of $X$. Consider the short exact sequence

$$0 \to \mathcal{J}_Y^2 \to \mathcal{J}_Y \to \mathcal{J}_Y/\mathcal{J}_Y^2 \to 0.$$ 

When $Y$ is a local complete intersection of codimension $d$, the quotient $N^*_Y = \mathcal{J}_Y/\mathcal{J}_Y^2$ is a locally trivial analytic sheaf of rank $d$ with support on $Y$, that is, a holomorphic vector bundle of rank $d$ over $Y$. The dual bundle $N_Y$ of $N^*_Y$ is by definition the normal bundle of $Y$ in $X$; in the non singular case this coincides with the usual definition of $N_Y$.

Suppose now that $X$ is Stein and $Y \subset X$ is a local complete intersection of codimension $d$ in $X$ with normal bundle $N_Y$. If $Y$ is a complete intersection then $N_Y$ is trivial (since its dual bundle $N^*_Y = \mathcal{J}_Y/\mathcal{J}_Y^2$ is generated by the images of the generators of $\mathcal{J}_Y$ and hence is trivial). The following partial converse was obtained in 1966 by Forster and Ramspott [FRa] by using the Oka-Grauert homotopy principle ([Gra], [Car]):

Let $Y$ be a local complete intersection of codimension $d$ with trivial normal bundle in a Stein space $X$. Suppose that $U \subset X$ is an open set containing $Y$ and the functions $f = (f_1, \ldots, f_d) \in \mathcal{O}(U)^d$ generate $\mathcal{J}_Y$ on $U$. If there is a continuous map $\tilde{f}: X \to \mathbb{C}^d$ such that $\tilde{f} = f$ near $Y$ and $\tilde{f}^{-1}(0) = Y$, then $Y$ is a holomorphic complete intersection in $X$. Such $\tilde{f}$ always exists if $\dim Y < \dim X/2$, or if $X$ is contractible and $\dim Y \leq 2(\dim X - 1)/3$.

Furthermore, M. Schneider proved that for any local complete intersection $Y \subset X$ with trivial normal bundle the sheaf $\mathcal{J}_Y$ admits $d + 1$ generators (Theorem 2.5 in [Sch]).

Suppose now that $\Sigma$ is a closed complex subvariety of $\mathbb{C}^d$, $f: X \to \mathbb{C}^d$ a holomorphic map from a Stein manifold $X$ and $Y \subset X$ a connected component (or a union of such components) of $f^{-1}(\Sigma)$. When is it possible to modify $f$ to a holomorphic map $g: X \to \mathbb{C}^d$ such that $g^{-1}(\Sigma) = Y$ and $g - f$ vanishes to a given order on $Y$? A necessary condition is that we can modify $f$ to a continuous map with the required properties, and we are interested in the corresponding homotopy principle. Example 2 below shows that we must restrict the class of subvarieties $\Sigma$ to obtain positive
results. Denote by \( \text{Aut } \mathbb{C}^d \) the group of all holomorphic automorphisms of \( \mathbb{C}^d \).

**Definition 1.** — A closed complex subvariety \( \Sigma \subset \mathbb{C}^d \) is said to be tame if there is a \( \Phi \in \text{Aut } \mathbb{C}^d \) such that \( \Phi(\Sigma) \subset \Gamma = \{(z', z_d) \in \mathbb{C}^d : |z_d| \leq 1 + |z'|\} \).

Every proper complex algebraic subvariety of \( \mathbb{C}^d \) is tame. Conversely, a subvariety \( \Sigma \subset \mathbb{C}^d \) of pure dimension \( d - 1 \) contained in \( \Gamma \) is algebraic [Chi], and hence \( \Sigma^{d-1} \subset \mathbb{C}^d \) is tame if and only if it is equivalent to an algebraic subset by an automorphism of \( \mathbb{C}^d \). For discrete sets our notion of tameness coincides with that of Rosay and Rudin [RR].

1.3. **Theorem (Removal of intersections).** — Let \( \Sigma \) be a closed complex analytic subvariety of \( \mathbb{C}^d \) satisfying one of the following conditions:

(a) \( \Sigma \) is tame and \( \dim \Sigma \leq d - 2 \);

(b) a complex Lie group acts holomorphically and transitively on \( \mathbb{C}^d \setminus \Sigma \).

Let \( X \) be a Stein manifold, \( f : X \to \mathbb{C}^d \) a holomorphic map and \( Y \subset X \) a union of connected components of \( f^{-1}(\Sigma) \). If there is a continuous map \( \tilde{f} : X \to \mathbb{C}^d \) which equals \( f \) in a neighborhood of \( Y \) and satisfies \( \tilde{f}^{-1}(\Sigma) = Y \), then for each \( r \in \mathbb{N} \) there is a holomorphic map \( g : X \to \mathbb{C}^d \) such that \( g^{-1}(\Sigma) = Y \) and \( g - f \) vanishes to order \( r \) along \( Y \). Such \( g \) always exists if \( \dim X < 2(d - \dim \Sigma) \), or if \( X \) is contractible and \( \dim Y \leq 2(d - \dim \Sigma - 1) \).

The theorem on complete intersections [FRa] mentioned above corresponds to the special case of Theorem 1.3 with \( \Sigma = \{0\} \subset \mathbb{C}^d \); in this case we have \( \dim X = \dim Y + d \), \( \dim \Sigma = 0 \), and hence the dimension conditions in both theorems agree.

Theorem 1.3 is proved in Section 4. Using the Oka-Grauert-Gromov homotopy principle from [Gro], [FP1], [FP2] we reduce it to an extension problem for continuous maps to which we then apply some standard results from the obstruction theory. The following example shows that Theorem 1.3 fails for non-tame subvarieties of \( \mathbb{C}^d \), independently of their codimension.

**Example 2.** — For each \( d \geq 1 \) there is a discrete set \( \Sigma \subset \mathbb{C}^d \) such that every holomorphic map \( g : \mathbb{C}^d \to \mathbb{C}^d \setminus \Sigma \) has rank at most \( d - 1 \). When \( d = 1 \), this holds already if \( \Sigma \) contains two points (the complement is then
hyperbolic); for $d > 1$ such sets were constructed by Rosay and Rudin [RR]. For such $\Sigma$ the conclusion of Theorem 1.3 fails for $Y = \{0\} \subset \mathbb{C}^d = X$. □

We observe that complements of tame subvarieties of codimension at least two admit Fatou-Bieberbach domains; for proof see Section 4:

1.4. PROPOSITION. — For each tame complex subvariety $\Sigma \subset \mathbb{C}^d$ of codimension at least two there exists an injective holomorphic map $F: \mathbb{C}^d \to \mathbb{C}^d \setminus \Sigma$ (a Fatou-Bieberbach map). If $0 \notin \Sigma$, we can choose $F$ such that $F(0) = 0$ and $F$ is tangent to the identity at 0 to arbitrary finite order. The same is true if $\Sigma$ is a compact subset of $\mathbb{C}^d$ whose polynomial hull does not contain the origin.

1.5. COROLLARY. — Let $\Sigma \subset \mathbb{C}^d \setminus \{0\}$ be as in Proposition 1.4. If $Y \subset X$ is a complete intersection of codimension $d$ in a complex space $X$, we can choose generators $f_1, \ldots, f_d$ of $J_Y$ such that the map $f = (f_1, \ldots, f_d): X \to \mathbb{C}^d$ avoids $\Sigma$.

Proof. — If $g = (g_1, \ldots, g_d)$ is any set of generators for $J_Y$ and $F$ satisfies Proposition 1.4, the components of the map $f = F \circ g: X \to \mathbb{C}^d$ are generators of $J_Y$ and we have $f(X) \subset \mathbb{C}^d \setminus \Sigma$. □

We conclude this introduction by mentioning two open problems.

Problem 1 (Murthy). — Let $Y \subset \mathbb{C}^n$ be a local holomorphic complete intersection with trivial normal bundle. Is $Y$ a complete intersection in $\mathbb{C}^n$? In particular, is every closed complex submanifold $Y \subset \mathbb{C}^n$ with trivial normal bundle a holomorphic complete intersection in $\mathbb{C}^n$? The first open case to consider is five dimensional submanifolds in $\mathbb{C}^6$ [Sch]. The answer is negative for differential complete intersections (Example 1.1 in [BK]).

Problem 2. — If the answer to Problem 1 is negative in general, we may ask whether there exists a closed complex submanifold $Y \subset \mathbb{C}^n$ with the following properties:

(a) the complex normal bundle of $Y$ in $\mathbb{C}^n$ is trivial,
(b) $Y$ is a differential complete intersection in $\mathbb{C}^n$, but
(c) $Y$ is not a holomorphic complete intersection in $\mathbb{C}^n$.

The paper is organized as follows. In Section 2 we collect some
preliminary material on vector bundles. In Section 3 we prove Theorems 1.1 and 1.2. In Section 4 we prove Theorem 1.3 and Proposition 1.4.

2. Preliminaries.

We begin by recalling some basic facts on real and complex vector bundles over CW-complexes; the proofs can be found in [Hus]. The results concerning complex vector bundles remain true for holomorphic vector bundles over Stein spaces in view of the Oka–Grauert principle [Gra], [Car] and the fact that any n-dimensional Stein space is homotopy equivalent to an n-dimensional CW-complex [Ham].

We denote by Vect\textsuperscript{k}_{\mathbb{R}}(X) (resp. Vect\textsuperscript{k}_{\mathbb{C}}(X)) the topological isomorphism classes of real (respectively complex) vector bundles of rank k over a CW-complex X. If X is a Stein space then by Grauert’s theorem [Gra], Vect\textsuperscript{k}_{\mathbb{C}}(X) coincides with the equivalence classes of holomorphic vector bundles of rank k over X. By T\textsuperscript{k}_{\mathbb{R}} (resp. T\textsuperscript{k}_{\mathbb{C}}) we denote the trivial real (respectively complex) vector bundle of rank k over a given base (which will always be clear from the context).

2.1. **THEOREM.** — Let X be an n-dimensional CW-complex. The map

\[ \text{Vect}_\mathbb{R}^k(X) \to \text{Vect}_\mathbb{R}^{k+r}(X), \quad E \to E \oplus T^r_\mathbb{R} \quad (k, r \geq 1) \]

is surjective if \( k \geq n \) and is bijective if \( k \geq n + 1 \).

2.2. **THEOREM.** — Let X be an n-dimensional CW-complex. The map

\[ \text{Vect}_\mathbb{C}^k(X) \to \text{Vect}_\mathbb{C}^{k+r}(X), \quad E \to E \oplus T^r_\mathbb{C} \quad (k, r \geq 1) \]

is surjective when \( k \geq \lfloor n/2 \rfloor \) and is bijective when \( k \geq \lceil (n+1)/2 \rceil \). In particular, if \( E \to X \) is a nontrivial complex vector bundle of rank \( k \geq \lceil (n+1)/2 \rceil \), the bundle \( E \oplus T^r_\mathbb{C} \) is nontrivial for each \( r \in \mathbb{N} \).

**Remark.** — Theorem 2.2 shows that any complete intersection submanifold \( Y \) in \( \mathbb{C}^n \) is parallelizable, since \( TY \oplus N_Y = T\mathbb{C}^n|_Y = T^n \mathbb{C} \) and \( N_Y \) trivial implies \( TY \) trivial. Likewise, any real submanifold \( Y \subset \mathbb{R}^N \) which is a differential complete intersection is stably parallelizable, i.e., \( TY \oplus T^1_\mathbb{R} \) is trivial.

We shall also need the following result from [BK].
2.3. THEOREM. — Each smooth submanifold \( Y \subset \mathbb{R}^n \) of codimension \( d \in \{1, 2, 4, 8\} \) and with trivial normal bundle is a differential complete intersection in \( \mathbb{R}^n \).

Proof. — We recall the proof from [BK] for the sake of completeness. By triviality of \( N_Y \) there is an open set \( U \subset \mathbb{R}^n \) containing \( Y \) and a smooth map \( f = (f_1, \ldots, f_d): U \to \mathbb{R}^d \) which defines \( Y \) as a smooth complete intersection in \( U \). Let \( U^* = U \setminus Y \) and let \( \phi: U^* \to S^{d-1} \) (the unit sphere in \( \mathbb{R}^d \)) be defined by \( \phi(x) = f(x)/|f(x)| \). If \( d \in \{2, 4, 8\} \), \( S^{d-1} \) admits \( d - 1 \) linearly independent vector fields \( v_2, \ldots, v_d \). For \( x \in U^* \) we denote by \( A(x) \) the \( d \times d \) matrix whose first column is \( f(x) \) and the subsequent columns are \( v_j \circ \phi(x) \), \( 2 \leq j \leq d \). Let \( E \to \mathbb{R}^n \) be the smooth rank \( d \) vector bundle obtained by patching the trivial bundles over the open covering \( (U, \mathbb{R}^n \setminus Y) \) of \( \mathbb{R}^n \) by the map \( A: U \setminus Y \to GL(d, \mathbb{R}) \). Since \( f = Ae_1 \) for \( e_1 = (1, 0, \ldots, 0)^t \), the maps \( f \) and \( e_1 \) patch together to a global section \( \tilde{f}: \mathbb{R}^n \to E \) which has no zeros outside of \( U \). Since every vector bundle over \( \mathbb{R}^n \) is trivial, \( \tilde{f} \) gives rise to a smooth map \( \mathbb{R}^n \to \mathbb{R}^d \) which defines \( Y \) as a complete intersection in \( \mathbb{R}^n \).

Remark. — Theorem 2.3 holds (with the same proof) if we replace \( \mathbb{R}^n \) by any contractible smooth manifold. However, the argument does not apply if \( d \notin \{1, 2, 4, 8\} \), and the authors of [BK] conjectured that the conclusion holds only for the indicated values of \( d \). \( \square \)

The following result justifies Example 1 in the introduction.

2.4. PROPOSITION. — There exists a Stein manifold \( X \) of dimension four and a closed complex submanifold \( Y \subset X \) of dimension two which is homotopy equivalent to the two-sphere such that \( Y \) is a differential complete intersection but not a holomorphic complete intersection in \( X \).

Proof. — We take \( X \) to be the total space of a rank two holomorphic vector bundle over a two dimensional Stein manifold \( Y \) such that the bundle is trivial as a real vector bundle but non-trivial as a complex vector bundle over \( Y \). Its zero section, which we identify with \( Y \), is then a differential complete intersection but not a holomorphic complete intersection in \( X \). To obtain such a bundle we let \( S \) be the Riemann sphere and set \( E = TS \oplus T^1_C \to S \), where \( TS \) is the holomorphic tangent bundle of \( S \). Since \( TS \) is non-trivial and the base has dimension two, Theorem 2.2 shows that \( E \) is non-trivial as a complex vector bundle. However, as a real
bundle we have $E = (TS \oplus T^1_S) \oplus T^1_R$ which is trivial. We now take $Y$ to be a Stein complexification of $S$, containing $S$ as a maximal real submanifold, and we extend $E$ to a holomorphic vector bundle $X \to Y$.

It is instructive to carry out the above procedure explicitly by defining a non-trivial complex structure on the trivial rank four bundle $T^4_R \to S$. The last part of the argument below is essentially the same one which can be used to prove Theorem 2.2.

Explicit construction of a non-trivial complex structure on $T^4_R$ over the 2-sphere: Let $x = (x_1, x_2, x_3, x_4)$ be real coordinates on $\mathbb{R}^4$ and let $\{e_j; 1 \leq j \leq 4\}$ be the corresponding standard basis of $T_x \mathbb{R}^4$. Let $S \subset \{0\} \times \mathbb{R}^3 \subset \mathbb{R}^4$ be the unit hypersurface sphere in the hyperplane $x_1 = 0$, and let $V = T\mathbb{R}^4|_S \cong S \times \mathbb{R}^4$. We can equip $V$ with the structure of a rank 2 complex vector bundle over $S$ by choosing a map $J: S \to GL(4, \mathbb{R})$ satisfying $J^2_x = -I$ for each $x \in S$. One such choice is $J^0_x e_1 = e_2$, $J^0_x e_3 = e_4$; in this structure $V \to S$ is a trivial $\mathbb{C}$-vector bundle over $S$. Another choice is obtained by starting with

$$J^1_x e_1 = x_2 e_2 + x_3 e_3 + x_4 e_4, \quad x = (0, x_2, x_3, x_4) \in S.$$  

Let $V^1_x \subset V_x$ be the real 2-plane spanned by $e_1$ and $J^1_x e_1$, and let $V^2_x \subset V_x$ denote the orthogonal complement to it. Notice that $V^2_x$ is an oriented plane bundle, we can choose an orientation preserving $J^1_x: V^2_x \to V^2_x$, depending continuously on $x \in S$ and such that $J^2_x = -I$ on $V^2_x$. (The choice is unique if we require that $J^1_x$ be orthogonal.) We then extend $J^1_x$ by linearity to $V_x$.

We claim that the $\mathbb{C}$-bundle $(V, J)$ over $S$ is not equivalent to the trivial $\mathbb{C}$-bundle $(V, J^0)$. Suppose on the contrary that there exists an equivalence $\varphi: \mathbb{R}^3 \to GL(4, \mathbb{R})$ between the two bundles, meaning that $\varphi^0 A^{-1} = J$. The group preserving $J^0$ is precisely $GL(2, \mathbb{C})$, and hence for any map $B: S \to GL(2, \mathbb{C})$ we have

$$J^1 = A J^0 A^{-1} = A B J^0 B^{-1} A^{-1} = (AB) J^0 (AB)^{-1}.$$  

We claim that we can choose $B$ such that $B^{-1} A^{-1} e_1 = e_1$ on $S$. Since $\mathbb{R}^4 \setminus \{0\} \cong S^3$, every map $S = S^2 \to \mathbb{R}^4 \setminus \{0\}$ is homotopic to a constant map. Thus there is a homotopy $v_t: S \to \mathbb{R}^4 \setminus \{0\}$ ($t \in [0, 1]$) from $v_0 = e_1$ to $v_1 = A^{-1} e_1$. Denote by $\tau: GL(2, \mathbb{C}) \to \mathbb{R}^4 \setminus \{0\}$ the map $\tau(B) = B e_1$. Clearly this map is a Serre fibration, i.e., it has the homotopy lifting property. Thus there is a homotopy $B_t: S \to GL(2, \mathbb{C})$ ($t \in [0, 1]$), with $B_0 = I$, satisfying $B_t e_1 = v_t$ for each $t \in [0, 1]$. At $t = 1$ we get the desired map $B = B_1$ satisfying $B e_1 = A^{-1} e_1$.  

Annales de L'Institut Fourier
Write $C = AB$; hence $J = CJ^0C^{-1}$. By construction we have $Ce_1 = e_1$ and $Ce_2 = CJ^0e_1 = Je_1$. Thus $C$ maps the trivial subbundle $U = \mathbb{R}^2 \times \{0\}^2 \subset V$ onto the subbundle $V^1 \subset V$, and hence it induces an isomorphism of quotient bundles $V/U \cong V/V^1 \cong V^2 \cong TS$. This is a contradiction since the first bundle is trivial while the second is not.

3. Proof of Theorems 1.1 and 1.2.

**Proof of Theorem 1.2.** — Let $F: Y \rightarrow \mathbb{C}^n$, $n = m + d$, be any proper holomorphic embedding. We identify $Y$ with the submanifold $F(Y) \subset \mathbb{C}^n$ and denote by $N_Y$ its holomorphic normal bundle. By the Oka-Cartan theory we have a holomorphic splitting $T\mathbb{C}^n|_Y \cong TY \oplus N_Y$ [GR]. Since $Y$ is a Stein manifold of dimension $m$, it is homotopy equivalent to a real $m$-dimensional CW-complex. Since $TY$ is a trivial real bundle of rank $2m$ over $Y$, Theorem 2.1 shows that its complement $N_Y$ is also real trivial provided that $2d > m$. Furthermore, the real codimension of $Y$ is $2d$ which is assumed to be either 4 or 8 and hence $Y$ is a differential complete intersection in $\mathbb{C}^n$ by Theorem 2.3. On the other hand, since $TY$ is non-trivial as a complex bundle over $Y$, Theorem 2.2 implies that $N_Y$ is also a non-trivial complex vector bundle and hence $Y$ is not a holomorphic complete intersection in any open set $U \subset \mathbb{C}^n$ containing $Y$. (There are no restrictions on $d$ and $m$ in the last argument). $\square$

In the proof of Theorem 1.1 we shall need the following:

3.1. **Proposition.** — For any compact orientable two dimensional surface $M$ of genus $g \geq 2$ there exists a three dimensional Stein manifold which is homotopically equivalent to $M$ and whose tangent bundle is trivial as a real vector bundle but is non-trivial as a complex vector bundle.

**Proof.** — Let $M$ be any surface as in the proposition; such $M$ is the connected sum of $g \geq 2$ tori. Its tangent bundle $TM$ is non-trivial, but $TM \oplus T^1_{\mathbb{R}}$ is trivial since $M$ embeds as a real hypersurface in $\mathbb{R}^3$. By Theorem 1.8 in [Forl] there exists a smooth (even real-analytic) embedding $M \hookrightarrow \mathbb{C}^2$ which is totally real except at finitely many complex tangent points which are hyperbolic in the sense of Bishop [Bis] and such that the embedded submanifold $M \subset \mathbb{C}^2$ has arbitrary small Stein neighborhoods $\Omega \subset \mathbb{C}^2$ with a deformation retraction $\pi: \Omega \rightarrow M$. 

TOME 51, (2001) FASCICULE 2
We endow $TM$ with the structure of a complex line bundle and take $E = \pi^*(TM) \to \Omega$. By the Oka–Grauert theorem [Gra] the bundle $p: E \to \Omega$ has an equivalent structure of a holomorphic vector bundle. In the present situation we can obtain such a structure quite explicitly as follows. Assume (as we may) that the embedding $M \subset C^2$ is real-analytic. We can represent the bundle $TM$ by a 1-cocycle defined by real-analytic functions $c_{ij}: U_{ij} \to C \setminus \{0\}$ on a (finite) open covering $\mathcal{U} = \{U_i\}$ of $M$ such that the closure of each of the sets $U_{ij} = U_i \cap U_j$ for $i \neq j$ is contained in the totally real part of $M$ (we only need to avoid the finitely many complex tangents in $M$). The complexifications of the functions $c_{ij}$ now determine a holomorphic line bundle structure on $E$ over an open neighborhood of $M$ in $C^2$.

We claim that the total space $E$ of this holomorphic vector bundle satisfies Proposition 3.1. Since the base $\Omega$ is Stein, $E$ is also Stein. Clearly $E$ is homotopy equivalent to $\Omega$ and hence to $M$. We identify $\Omega$ with the zero section of $E$. The tangent bundle of $E$ equals $TE = p^*(TE|_{\Omega})$, where $TE|_{\Omega} = T\Omega \oplus E = T^2_\mathbb{C} \oplus E$. Since $E \to \Omega$ is a non-trivial bundle and the base $\Omega$ is homotopic to the surface $M$, Theorem 2.2 shows that $TE|_{\Omega}$ is non-trivial as a complex vector bundle over $\Omega$, and hence $TE$ is a non-trivial complex vector bundle. On the other hand, as real vector bundles we have $TE|_{\Omega} = T^4_\mathbb{R} \oplus E = T^2_\mathbb{R} \oplus (T^2_\mathbb{R} \oplus E)$. We have already observed that the second summand is trivial and hence $TE|_{\Omega}$ is a trivial real bundle. Therefore $TE$ is also trivial as a real bundle over $E$.

Proof of Theorem 1.1. — Let $Y$ be a Stein manifold satisfying Proposition 3.1. By the embedding theorem of Eliashberg and Gromov [EGr] and Schürmann [Schür] there exists a proper holomorphic embedding $Y \hookrightarrow C^5$. By Theorem 1.2 $Y$ is then a differential complete intersection but not a holomorphic complete intersection in $C^5$. The same argument applies to any embedding $Y \hookrightarrow C^j$.

Proof of Proposition 1.4. — Consider first the case when $\Sigma \subset C^d$ is a tame subvariety of dimension at most $d - 2$. For $1 \leq j \leq d$ we denote by $\pi_j: C^d \to C_{d-1}^j$ the projection onto the coordinate hyperplane $\{z_j = 0\}$. Tameness of $\Sigma$ implies that, after a biholomorphic change of coordinates on
In $\mathbb{C}^d$, the restriction of $\pi_j$ to $\Sigma$ is proper for each $j$, and hence $\Sigma_j = \pi_j(\Sigma)$ is a proper closed analytic subset of $\mathbb{C}_j^{d-1}$. By translation, we may assume that $\Sigma_j$ does not contain the origin for any $j$. Choose a holomorphic function $g_j$ on $\mathbb{C}_j^{d-1}$ such that $g_j(0) = -\log 2$ and $g_j = 0$ on $\Sigma_j$, and set

$$\Phi_j(z) = (z_1, \ldots, z_{j-1}, e^{g_j(z_j)}z_j, z_{j+1}, \ldots, z_d)$$

where $\hat{z}_j = (z_1, \ldots, z_{j-1}, z_{j+1}, \ldots, z_d)$. Then $\Phi = \Phi_1 \circ \Phi_2 \circ \cdots \circ \Phi_d \in \text{Aut } \mathbb{C}^d$, $\Phi$ restricts to the identity on $\Sigma$, $\Phi(0) = 0$, and $D\Phi(0) = \frac{1}{2}I$. Thus $0 \in \mathbb{C}^d$ is an attracting fixed point of $\Phi$ whose basin of attraction is a Fatou-Bieberbach domain $\Omega \subset \mathbb{C}^d \setminus \Sigma$. We obtain the corresponding Fatou-Bieberbach map $F: \mathbb{C}^d \to \Omega$ as in [RR].

If $K$ is a compact subset in $\mathbb{C}^d$ whose polynomial hull does not contain the origin, we can construct a Fatou-Bieberbach map $F: \mathbb{C}^d \to \mathbb{C}^d \setminus K$ by the push-out method of Dixon and Esterle [DE] (see also [For2]). Here is the outline. Replacing $K$ by $\hat{K}$ we may assume that $K$ is polynomially convex and $0 \notin K$. Denote by $B_r$ the closed ball of radius $r$ in $\mathbb{C}^d$. Proposition 2.1 in [For2] (or the results in [FRo]) gives an automorphism $G_0 \in \text{Aut } \mathbb{C}^d$ which is tangent to identity to a given order $r$ at $0$ and satisfies $G_0(K) \cap B_1 = \emptyset$. Set $K_1 = G_0(K)$. Next we choose $\Phi_1 \in \text{Aut } \mathbb{C}^d$ which approximates the identity map on $B_1$, is tangent to the identity at $0$ and satisfies $\Phi_1(K_1) \cap B_2 = \emptyset$, and we let $G_1 = \Phi_1 \circ G_0$. Continuing inductively we obtain a sequence $G_j \in \text{Aut } \mathbb{C}^d$ ($j \in \mathbb{Z}_+$) which converges on some domain $\Omega \subset \mathbb{C}^d$ to a biholomorphic map $G: \Omega \to \mathbb{C}^d$ of $G$ onto $\mathbb{C}^d$ (Proposition 5.1 in [For2]). By construction $G$ is tangent to the identity to order $r$ at $0$ and $K \cap \Omega = \emptyset$. The map $F = G^{-1}: \mathbb{C}^d \to \Omega$ satisfies Proposition 1.4.

Proof of Theorem 1.3. — We use the same notation as in the statement of the theorem. Let $\mathcal{J}_\Sigma$ be the sheaf of ideals of $\Sigma \subset \mathbb{C}^d$ and let $\mathcal{J}_Y$ be the sheaf of ideals of $Y \subset X$. We define an analytic sheaf of ideals $\mathcal{S}$ on $X$ as follows: at points $x \in Y$ we take $\mathcal{S}_x$ to be the pull-back of $\mathcal{J}_\Sigma, f(x)$ by $f$, and for $x \in X \setminus Y$ we take $\mathcal{S}_x = \mathcal{O}_{X,x}$. More precisely, if $x \in Y$ and $\mathcal{J}_\Sigma$ is generated by functions $h_1, \ldots, h_m$ in some neighborhood of $f(x)$ in $\mathbb{C}^d$, we take the functions $h_j \circ f$ ($1 \leq j \leq m$) as the generators of $\mathcal{S}$ in a neighborhood of $x$. Clearly $\mathcal{S}$ is a coherent analytic sheaf of ideals on $X$ and $\mathcal{O}_{X}/\mathcal{S}$ is supported on $Y$.

Choose $r \in \mathbb{N}$ and let $\mathcal{R} = \mathcal{S}\mathcal{J}_Y^r$; this is also a coherent sheaf of ideals on $X$ which coincides with $\mathcal{O}_{X}$ on $X \setminus Y$. By the Oka-Cartan theory there are finitely many global sections $\xi_1, \ldots, \xi_k$ of $\mathcal{R}$ such that $Y = \{x \in X: \xi_j(x) = 0, \ 1 \leq j \leq k\}$. (We do not require that the $\xi_j$'s
We seek a map $g : X \to \C^d$ satisfying Theorem 1.3 in the form
\begin{equation}
    g(x) = f(x) + \sum_{j=1}^{k} \xi_j(x) g_j(x) = f(x) + G(x) \xi(x),
\end{equation}
where $G(x) = (g_1(x), \ldots, g_k(x))$ is a holomorphic $d \times k$ matrix-valued function and $\xi = (\xi_1, \ldots, \xi_k)^t$. For any choice of $G$ the map $g = f + G\xi$ agrees with $f$ to order $r + 1$ along $Y$. Our goal is to choose $G$ such that $g^{-1}(\Sigma) = Y$. Define a holomorphic map $\Phi : X \times \C^{dk} \to \C^d$ by
\begin{equation}
    \Phi(x, v_1, \ldots, v_k) = f(x) + \sum_{j=1}^{k} \xi_j(x)v_j \quad (x \in X, v_1, \ldots, v_k \in \C^d)
\end{equation}
and let
\begin{equation}
    \widetilde{\Sigma} = \Phi^{-1}(\Sigma) \setminus (Y \times \C^{dk}).
\end{equation}
Then the map $g = f + G\xi$ satisfies Theorem 1.3 if and only if $G$ is holomorphic and its graph in $X \times \C^{dk}$ avoids $\widetilde{\Sigma}$ defined by (3).

Observe that for each fixed $x \in X \setminus Y$ the map $\Phi(x, \cdot) : \C^{dk} \to \C^d$ is an affine surjection, while for $x \in Y$ we have $\Phi(x, \cdot) = f(x)$ (hence $Y \times \C^{dk} \subset \Phi^{-1}(\Sigma)$). Let $p : X \times \C^{dk} \to X$ denote the base projection. We shall need the following lemma.

4.1. LEMMA. — The set $\widetilde{\Sigma}$ defined by (3) is a closed complex subvariety of $X \times \C^{dk}$. Moreover, for each point $a \in X \setminus Y$ there is a neighborhood $U \subset X \setminus Y$ of $a$ and a biholomorphic self-map $\Psi$ of $\widetilde{U} = U \times \C^{dk}$, with $p \circ \Psi = p$, such that $\Psi(x, \cdot)$ is affine linear for each $x \in U$ and $\Psi(\widetilde{\Sigma} \cap \widetilde{U}) = U \times (\Sigma \times \C^{d(k-1)})$.

Proof. — By definition $\widetilde{\Sigma}$ is a closed complex subvariety in $(X \setminus Y) \times \C^{dk}$. The second statement follows immediately from the observation that $\Phi(x, \cdot) : \C^{dk} \to \C^d$ is an affine surjection for any $x \in X \setminus Y$ and hence is locally (with respect to the base) equivalent to the projection of $\C^{dk}$ onto $\C^d \times \{0\}^{d(k-1)}$.

It remains to show that $\widetilde{\Sigma}$ is closed in $X \times \C^{dk}$. We need to show that, as $x \in X \setminus Y$ approaches a point $x_0 \in Y$, the fibers $\widetilde{\Sigma}_x$ leave any compact subset of $\C^{dk}$. Choose a neighborhood $V \subset \C^d$ of the point $f(x_0)$ and holomorphic functions $h = (h_1, \ldots, h_m)$ on $V$ which generate the ideal sheaf $\mathcal{R}$ on $V$. Also choose a neighborhood $U \subset X$ of $x_0$ with $f(U) \subset V$. Let $\xi_1, \ldots, \xi_k$ be sections of the sheaf $\mathcal{R}$ as above. By Taylor expansion of
h at the point \( f(x) \) for \( x \in U \) and \( v = (v_1, \ldots, v_k) \in \mathbb{C}^{dk} \) we get

\[
h \circ \Phi(x, v) = h \left( f(x) + \sum_{j=1}^{k} \xi_j(x)v_j \right)
\]

\[
= h(f(x)) + \sum_{|\alpha| \geq 1} c_{\alpha} D^\alpha h(f(x)) \left( \sum_{j=1}^{k} \xi_j(x)v_j \right)^\alpha
\]

\[
= h(f(x)) + A(x, v)\xi(x),
\]

where \( A \) is a holomorphic \( d \times k \) matrix function. Denoting by \( \| \cdot \| \) the Euclidean norm on \( \mathbb{C}^d \) (and the corresponding matrix norm) we have

\[
\| h(\Phi(x, v)) \| \geq \| h(f(x)) \| - \| A(x, v) \| \cdot \| \xi(x) \|.\]

The components of \( h(f(x)) \) generate the sheaf \( S \) at each point of \( U \). Hence, as \( x \to x_0 \in Y \), the term \( \| \xi(x) \| \) is of size \( o(\| h(f(x)) \|) \) by the definition of the sheaf \( R = S\mathcal{F}^r \). Hence for each \( C > 0 \) there is a neighborhood \( U_C \subset U \) of \( x_0 \) such that for all \( x \in U_C \) and \( v \in \mathbb{C}^{dk} \) with \( \| v \| \leq C \) we have \( \| h \circ \Phi(x, v) \| \geq \| h(f(x)) \|/2 \). and hence \( \Phi(x, v) \in \Sigma \) if and only if \( x \in Y \). Thus for \( x \in U_C \) the fiber \( \tilde{\Sigma}_x \) does not intersect the ball of radius \( C \) in \( \mathbb{C}^{dk} \). This proves that \( \tilde{\Sigma} \) is closed in \( X \times \mathbb{C}^{dk} \).

We continue with the proof of Theorem 1.3. The assumptions on \( \Sigma \) imply that the complement \( \mathbb{C}^d \setminus \Sigma \) admits a spray in the sense of Gromov (see [FP1] and Lemma 7.1 in [FP2]). From this and the second statement in Lemma 4.1 it follows that the holomorphic submersion \( h: Z = (X \times \mathbb{C}^{dk}) \setminus \tilde{\Sigma} \to X \) admits a fiber dominating spray in a small neighborhood of any point \( x \in X \setminus Y \) ([Gro] or Definition 1.1 in [FP2]). By Theorem 1.2 in [FP2] (see also [Gro], 4.5 Main Theorem) the homotopy principle holds for sections of \( Z \), meaning that any continuous section \( G: X \to Z \) can be deformed to a holomorphic section.

A continuous extension \( \tilde{f}: X \to \mathbb{C}^d \) of \( f \) as in Theorem 1.3 can be lifted to a continuous section \( \tilde{G}: X \to Z \) which is holomorphic near \( Y \) (see Lemma 8.1 in [FP2]). The homotopy principle gives a holomorphic section \( G: X \to Z \) such that the corresponding map \( g: X \to \mathbb{C}^d \) (2) satisfies Theorem 1.3.

In the remainder we investigate the existence of a continuous extension \( \tilde{f} \) using the obstruction theory (see e.g. Section V.5 in [Whi]). By [Ham] the subvariety \( Y \) has a closed neighborhood \( A \subset X \) such that the pair \( (X, A) \) is homotopy equivalent to a relative CW-complex of dimension \( n = \dim X \) and \( Y \) is a deformation retraction of \( A \). Moreover, we may
choose $A$ so small that $\{x \in A : f(x) \in \Sigma\} = Y$. Hence $f$ maps $A^* = A \setminus Y$ to $\Omega = \mathbb{C}^d \setminus \Sigma$, and we wish to find an extension of $f$ to a map from $X^* = X \setminus Y$ to $\Omega$.

The pair $(X^*, A^*)$ can be represented by the same relative CW-complex as $(X, A)$. Denote by $X_q$ its $q$-dimensional skeleton, so our goal is to extend $f$ to a map $X_0 \to \Omega$. We begin by extending $f$ to the zero-skeleton $X_0$ by arbitrarily prescribing the values at the points of $X_0$. Since $\Omega$ is connected, we can further extend to a map $f_1 : X_1 \to \Omega$. Suppose inductively that $f$ has already been extended to $f_q : X_q \to \Omega$ for some $q \geq 1$.

The next skeleton $X_{q+1}$ is obtained by attaching $(q + 1)$-cells $e_{q+1}$ to $X_q$ by maps $\partial e_{q+1} \to X_q$. Composing this attaching map with $f_q : X_q \to \Omega$ we obtain for each such cell $e_{q+1}$ a map $\partial e_{q+1} \to \Omega$ which defines an element of the fundamental group $\pi_q(\Omega)$. In this way we obtain a singular cochain $c^{q+1} \in \Gamma^{q+1}(X^*, A^*; \pi_q(\Omega))$ (which is in fact a $(q + 1)$-cocycle, called the obstruction cocycle), and $f_q$ extends to a map $f_{q+1} : X_{q+1} \to \Omega$ if and only if $c^{q+1} = 0$.

In our case we have $\pi_q(\Omega) = \pi_q(\mathbb{C}^d \setminus \Sigma) = 0$ for $1 \leq q \leq 2s - 2$, where $s = d - \dim \Sigma$. This implies that $f$ can be extended to the skeleton $X_{2s-1}$. Hence, if $\dim X < 2s = 2(d - \dim \Sigma)$, we have an extension $\tilde{f} : X \setminus Y \to \mathbb{C}^d \setminus \Sigma$ as required.

Assume now that $X$ is contractible (e.g., $X = \mathbb{C}^n$). We shall use the following more precise result from obstruction theory ([Whi], Theorem V.5.14):

Let $f_q : X_q \to \Omega$ for some $q \geq 1$. Then $f_q|_{X_{q-1}}$ can be extended to a map $f_{q+1} : X_{q+1} \to \Omega$ if and only if $\gamma^{q+1}(f) = [c^{q+1}] = 0 \in H^{q+1}(X^*, A^*; \pi_q(\Omega))$, i.e., the cohomology class of the obstruction cocycle $c^{q+1}$ equals zero.

By excision we have $H^q(X^*, A^*; G) = H^q(X, A; G)$ for any abelian coefficient group $G$. Since $X$ is contractible, the long exact sequence for the cohomology of the pair $A \hookrightarrow X$ gives $H^{q+1}(X, A; G) = H^q(A; G)$ for $q \geq 1$. Furthermore, since $Y$ is a deformation retract of $A$ we have $H^q(A; G) = H^q(Y; G)$. Together we obtain

$$H^{q+1}(X^*, A^*; \pi_q(\Omega)) = H^q(Y; \pi_q(\Omega)), \quad q \geq 1.$$ 

Since $Y$ is a Stein manifold of dimension $m$, it is homotopy equivalent to an $m$-dimensional CW-complex and hence $H^q(Y; \pi_q(\Omega)) = 0$ for $q > m$. Thus, if $f : A^* \to \Omega$ admits an extension to the skeleton $X_{m+1}$, it also admits an extension to all higher dimensional skeleta and hence to $X^*$. Earlier we
have seen that there is an extension to $X_{2s-1}$ with $s = d - \dim \Sigma$. If we assume $m + 1 \leq 2s - 1$, we thus obtain a desired continuous extension of $f$ to $X^*$. This completes the proof of Theorem 1.3. \hfill \Box

Acknowledgements. — I wish to thank E.L. Stout for having brought to my attention the question answered by Theorem 1.1 and for stimulating discussions.
