GROUPS OF GIVEN INTERMEDIATE WORD GROWTH

by Laurent BARTHOLDI & Anna ERSCHLER (*)

Abstract. — We show that there exists a finitely generated group of growth \( \sim f \) for all functions \( f : \mathbb{R}_+ \to \mathbb{R}_+ \) satisfying \( f(2R) \leq f(R)^2 \leq f(\eta_+R) \) for all \( R \) large enough and \( \eta_+ \approx 2.4675 \) the positive root of \( X^3 - X^2 - 2X - 4 \). Set \( \alpha_- = \log 2 / \log \eta_+ \approx 0.7674 \); then all functions that grow uniformly faster than \( \exp(R^{\alpha_-}) \) are realizable as the growth of a group.

We also give a family of sum-contracting branched groups of growth \( \sim \exp(R^{\alpha}) \) for a dense set of \( \alpha \in [\alpha_-, 1] \).

Résumé. — Nous montrons qu’il existe un groupe de type fini de croissance \( \sim f \) pour n’importe quelle fonction \( f : \mathbb{R}_+ \to \mathbb{R}_+ \) satisfaisant \( f(2R) \leq f(R)^2 \leq f(\eta_+R) \) lorsque \( R \) est suffisamment grand, avec \( \eta_+ \approx 2.4675 \) la racine positive de \( X^3 - X^2 - 2X - 4 \). Soit \( \alpha_- = \log 2 / \log \eta_+ \approx 0.7674 \); alors toutes les fonctions qui croissent uniformément plus vite que \( \exp(R^{\alpha_-}) \) sont réalisables comme fonction de croissance d’un groupe.

Nous exhibons aussi une famille de groupes branchés contractants-pour-la-somme et de croissance \( \sim \exp(R^{\alpha}) \), pour un sous-ensemble dense d’\( \alpha \in [\alpha_-, 1] \).

1. Introduction

In [17], Grigorchuk discovered the first example of group with growth function strictly between polynomial and exponential. Recall that the growth function of a finitely generated group \( G \), generated by \( S \) as a semigroup, is

\[ v(R) = \# \{ g \in G \mid g = s_1 \cdots s_\ell, \ell \leq R, s_i \in S \}; \]

Keywords: Growth of groups, self-similar groups, groups acting on trees, wreath products.
Math. classification: 20E08, 20F65.
(*) The work is supported by the ERC starting grant GA 257110 “RaWG”, the ANR “DiscGroup” and the Courant Research Centre “Higher Order Structures” of the University of Göttingen.
it measures the volume of a ball of radius $R$ in the Cayley graph of $G$. This function depends on the choice of generating set $S$, but only mildly: say $v \sim v'$ if there is a constant $C > 0$ such that $v(R) \leq v'(CR)$ and $v'(R) \leq v(CR)$ for all $R$ large enough. Then the $\sim$-equivalence class of $v$ is independent of the choice of $S$.

Grigorchuk’s result has been considerably extended, mainly by Grigorchuk himself, who constructed uncountably many groups of intermediate growth [18]. See [2, 1, 8, 16, 25, 27], the books [22, 26], or §1.3 for a brief overview.

Nevertheless, these results only give estimates on the growth of these groups. The first actual computation (up to $\sim$) of the growth function of a group of intermediate growth appears in [4]. In the present paper, we prove that a large class of intermediate growth functions are the growth functions of finitely generated groups. Our main result is:

**Theorem A.** — Let $\eta_+ \cong 2.4675$ be the positive root of $X^3 - X^2 - 2X - 4$. Let $f : \mathbb{R}_+ \rightarrow \mathbb{R}_+$ be a function satisfying

$$f(2R) \leq f(R)^2 \leq f(\eta_+ R) \text{ for all } R \text{ large enough.}$$

Then there exists a finitely generated group with growth $\sim f$.

Set $\alpha_- = \log 2/\log \eta_+ \approx 0.7674$; then every submultiplicative function that grows uniformly faster (in the sense of (1.1)) than $\exp(R^{\alpha_-})$ is equivalent to the growth function of a group.

The growth function of a group is necessarily nondecreasing and submultiplicative ($f(R + R') \leq f(R)f(R')$). Note that (1.1) implies that $f$ is equivalent to a monotone, submultiplicative function.

The following examples of functions all satisfy (1.1); so special cases of Theorem A give:

- for every $\alpha \in [\alpha_-, 1]$, there exists a group of growth $\sim \exp(R^\alpha)$;
- there exists groups of growth $\sim \exp(R/\log R)$, of growth $\sim \exp(R/\log \log R)$, of growth $\exp(R/\log \log \log R)$;
- there exists a group of growth $\sim \exp(R/A(R, R)^{-1})$, for $A(m, n)$ the Ackermann function; this last growth function is faster than any subexponential primitive-recursive function;
- for every $\alpha \leq \beta \in [\alpha_-, 1]$, there exists a group whose growth accumulates both at $\exp(R^\alpha)$ and at $\exp(R^\beta)$; this recovers a result by Brieussel, see [10] and §1.3.

**Remark 1.1.** — Furthermore, the group in Theorem A may be chosen to be of the form $W_\omega := A \wr_X G_\omega$ for a Grigorchuk group $G_\omega$ and a finite
group $A$; so it is residually finite as soon as $A$ is abelian. Briefly, $G_\omega$ is defined by its action on the set of infinite sequences $\{1, 2\}^\infty$, and $X$ is the orbit of $2^\infty$; the wreath product $W_\omega$ is the semidirect product $(\bigoplus_X A) \rtimes G_\omega$ for the natural action of $G_\omega$ on $X$. See §2 for details.

We give illustrations in §5.1 of sequences $\omega$ and the growth of the corresponding $W_\omega$.

If additionally $f(R)^{2+2\log \eta_+/\log R} \leq f(\eta_+ R)$ for all $R$ large enough, then there exists a torsion-free, residually finite, finitely generated group with growth $\sim f$. This group may be chosen to be an extension $\widetilde{G}_\omega$ of $G_\omega$ with abelian kernel. See §2.3 for details.

If $f$ is recursive, both of these groups may be chosen to be recursively presented, and to have solvable word problem; see §2.4 and Remark 5.4 for details.

We obtain more precise information on $W_\omega$ in some particular cases. A group $G$ is self-similar if it is endowed with a homomorphism $\phi : G \to G \wr \{1, \ldots, d\} S_d$ from $G$ to its permutational wreath product with the symmetric group $S_d$. The self-similar group $G$ is branched if there exists a finite-index subgroup $K \leq G$ such that $\phi(K)$ contains $K^d$; see §2 for more details, or [6] for a survey of consequences of the property. A self-similar group $G$ with proper metric $\| \cdot \|$ is sum-contracting if $\phi$ is injective and there exist constants $\lambda < 1$ (the contraction coefficient) and $C$ such that, writing $\phi(g) = \langle \langle g_1, \ldots, g_d \rangle \rangle \pi$, we have

$$\sum_{i=1}^d \|g_i\| \leq \lambda \|g\| + C.$$

A weaker contraction property “$\max \|g_i\| \leq \lambda \|g\| + C$” is used extensively to study self-similar groups, and is at the heart of all inductive proofs. A key observation by Grigorchuk in the early 1980’s was that the (somewhat counterintuitive) sum-contracting property holds for a finitely generated group (he showed that the group $G_{\text{Grig}}$ is sum-contracting with $d = 8$ and $\lambda = \frac{3}{4}$). Let $G$ be sum-contracting with contraction coefficient $\lambda$, and write $\eta = d/\lambda$. Then $G$ has growth at most $\exp(R^{\log d/\log \eta})$. Note that there are countably many sum-contracting groups, since such a group is determined by a choice of generators, of map $\phi$, and of which of the words of length $\leq C/(1 - \lambda)$ are trivial; see §2.4 for details.

**Theorem B.** — For every periodic sequence $\omega$ containing all three letters $0, 1, 2$ and every non-trivial finite group $A$, the finitely generated group $W_\omega := A \wr G_\omega$ is branched, sum-contracting, and has growth $\sim \exp(R^\alpha)$ for some $\alpha \in (0, 1)$. 

TOME 64 (2014), FASCICULE 5
Furthermore, the set of growth exponents $\alpha$ arising in this manner is dense in $[\alpha_-, 1]$. For these same $\alpha$, there exists a torsion-free self-similar, residually finite group $\hat{G}_\omega$ of growth $\sim \exp(R^\alpha \log R)$.

For example, $W_{012}$ has growth $\sim \exp(R^{\alpha_-})$, as was shown in [4]. The growth of $W_\omega$ for some other periodic sequences is as follows:

- For $\omega = 0\overline{2}12$, the growth of $W_\omega$ is $\sim \exp(R^{\log 2/\log \eta})$ with $\eta \sim 2.4057$ the positive root of $X^{12} - 39X^8 + 192X^4 - 256$.
- For $\omega = 0\overline{12}$, the growth of $W_\omega$ is $\sim \exp(R^{\log 2/\log \eta})$ with $\eta \sim 2.4283$ the positive real root of $X^6 + 5X^4 - 8X^2 - 16$.
- For $\omega = 0\overline{0}1$ and $t \to \infty$, the constant $\eta$ converges to $2$; more precisely, $\eta$ is the positive real root of $X^{3t} - (2t^2 + 1 + 2^{-1} - 1)X^{2t} + (2^{2t-1} + 2^{t+2})X^t - 2^{2t}$.

For $t$ large, that polynomial is approximately proportional to $(X/2)^{2t} - \frac{5}{2}(X/2)^t + \frac{1}{2}$, so $\eta \approx 2\sqrt{(5 + \sqrt{17})/4} \approx 2(1 + C/t)$ with $C = \log((5 + \sqrt{17})/4)$. This gives growth $\sim \exp(R^{1-C'/(t \log 2)})$ for $C' \to C$ as $t \to \infty$.

- For $\omega = 0\overline{1}12$ and $t \to \infty$, the constant $\eta$ also converges to $2$; more precisely, $\eta$ is the positive root of $X^{9t} - (4 \cdot 2^{3t} - 6 \cdot 2^{2t} + 6 \cdot 2^t - 1)X^{6t} - (2^{6t} - 6 \cdot 2^{5t} + 6 \cdot 2^{4t} - 4 \cdot 2^{3t})X^{3t} - 2^{6t}$. For $t$ large, that polynomial is approximately a multiple of $(X/2)^{6t} - 4(X/2)^{3t} - 1$, so $\eta \approx 2^{3}\sqrt{2 + \sqrt{5}} \approx 2(1 + C/t)$ with $C = \log(2 + \sqrt{5})$. This gives growth $\sim \exp(R^{1-C'/(t \log 2)})$ for $C' \to C$ as $t \to \infty$.

- If two finite sequences $\omega, \omega'$ may be obtained one from the other by cyclic permutation of the letters and permutation of the labels $0, 1, 2$, then the groups $W_\omega$ and $W_{\omega'}$ have commensurable direct powers, so their growth functions are equivalent. Furthermore, if $\omega$ is the reverse of $\omega'$, then $W_\omega$ and $W_{\omega'}$ have same growth; this also happens in other cases, e.g. $\omega = 000102211$ and $\omega' = 002002111$. The corresponding groups do not have commensurable direct powers, at least if $A$ has odd order; indeed such a commensuration would have to be an isomorphism that restricts to an isomorphism from $G_\omega$ to $G_{\omega'}$, but these last groups are not isomorphic, see [18].

These examples were obtained with the help of Proposition 4.4, by computing the characteristic polynomials of the corresponding products of matrices (3.1).
1.1. Growth of groups and wreath products

We define a partial order on growth functions \( v : \mathbb{R}_+ \to \mathbb{R}_+ \), as follows. Say \( v \preceq v' \) if, for some constants \( C, D > 0 \), we have \( v(R) \leq v'(CR) \) for all \( R > D \). Then \( v \sim v' \) if \( v \preceq v' \preceq v \).

We recall briefly the classical lemma that the equivalence class of a growth function is independent of the generating set. More generally, we shall consider weighted word metrics of groups, given by a weight function \( \| \cdot \| : S \to \mathbb{R}_+^* \) for a generating set \( S \). The norm of a word \( w = s_1 \cdots s_\ell \) is then \( \|s_1\| + \cdots + \|s_\ell\| \), and the norm of \( g \in G \) is the infimum of norms of words representing it. The growth function is then \( v(R) = \# \{ g \in G \mid R \geq \|g\| \} \).

Consider a group \( A \), and a group \( G \) acting on the right on a set \( X \). Their permutational wreath product is \( W = A \wr_X G := (\sum_X A) \rtimes G \), with the natural permutation action of \( G \) on \( \sum_X A \). If \( A, G \) are finitely generated and \( G \) acts transitively on \( X \), then \( W \) is finitely generated. Fix a basepoint \( \rho \in X \); then \( W \) is generated by \( S \cup T \), with \( S \) a generating set of \( G \) and \( T \) the set of functions \( X \to A \) that vanish outside \( \rho \) and take values in a fixed generating set of \( A \) at \( \rho \).

The growth of \( W \) is intimately related to the inverted orbit growth of \( G \) on \( X \): the maximum \( \Delta(R) \), over all words \( s_1 \cdots s_\ell \in S^* \) of norm at most \( R \), of \( \# \{ \rho s_1 \cdots s_\ell, \rho s_2 \cdots s_\ell, \ldots, \rho s_\ell, \rho \} \). This was already used in \cite{4} to determine the growth of \( W_{012} \), and in \cite{5} to prove that certain permutational wreath products have exponential growth.

1.2. Sketch of the argument

Let us consider infinite sequences \( \omega \) over the alphabet \( \{0, 1, 2\} \) which alternates appropriately in segments of the form \( (012)^i k \) and \( 2^i k \). For any such sequence, Grigorchuk constructed in \cite{18} a 4-generated group \( G_\omega = \langle a, b, c, d \rangle \) of intermediate growth, acting on the infinite binary rooted tree \( T \), see §2.1. The first generator permutes the two top-level branches of \( T \), while the next three fix an infinite ray \( \rho \) in \( T \) and permute branches in the immediate neighbourhood of \( \rho \) according to \( \omega \); the \( i \)th letter of \( \omega \) determines how \( b, c, d \) act on the neighbourhood of the \( i \)th point of \( \rho \).

Let \( X \) denote the orbit of \( \rho \) under \( G_\omega \), choose a non-trivial finite group \( A \), say \( \mathbb{Z}/2\mathbb{Z} \), and define \( W_\omega = A \rtimes_X G_\omega \), the permutational wreath product of \( A \) and \( G_\omega \); see §2.2.

We estimate the growth of \( W_\omega \) by bounding from above the word growth of \( G_\omega \) and by bounding from above and below the inverted orbit growth of
$G_\omega$ on $X$, as in [4]. The changes with respect to [4] may be summarized as follows: instead of considering a fixed group $G_\omega$, we consider a sequence of groups $G_i$, and a dynamical system relating optimal choices of metrics on them. We relate the growth of the $G_i$ to properties of the dynamical system. The example of $W_{\mathcal{U}_2}$ is recovered as a 3-periodic orbit in the dynamical system.

Let $G_i$ denote the group $G_{s_1 \ldots s_i \omega}$ for $s$ the shift map on sequences. There are then injective homomorphisms $\phi_i : G_i \to G_{i+1} \wr \mathcal{S}_2$. For each $i$ we consider a space of metrics on $G_i$, see §3. These metrics are specified by setting the lengths of $a, b, c, d$, and are naturally parameterized by the open 2-simplex. The boundary of the simplex corresponds to degenerate metrics, in which $\|a\| = 0$, while the corners of the simplex correspond to even more degenerate metrics, in which $\|a\| = \|x\| = 0$ for some $x \in \{b, c, d\}$. The scale of the metric is set by the condition $\|ab\| + \|ac\| + \|ad\| = 1$.

We select for each $i$ a metric $\|\cdot\|_i$ on $G_i$ and a parameter $\eta_i \in (2, 3)$, such that the map $\phi_i$ is coarsely $(2/\eta_i)$-Lipschitz (i.e. satisfies $\|\phi_i(g)\|_{i+1} \leq 2/\eta_i \|g\|_i + C$ for a constant $C$) with respect to the metric on $G_i$ and the $\ell_1$ metric on $G_{i+1} \times G_{i+1}$; see Lemma 3.3. The optimal choice of metrics is studied via a projective dynamical system on the simplex. In fact, $\eta_i$ depends analytically on $\|\cdot\|_i$ and the $i$th letter of $\omega$. Whenever $\omega$ has long constant subwords, the metrics degenerate towards the boundary of the simplex, but do so in a controlled manner; in particular, we make sure that the metrics never degenerate to a corner of the simplex.

We arrive at the heart of the argument. The first step is to deduce, in Proposition 3.6, an upper bound on the word growth of $G_i$, in terms of $\eta_1 \ldots \eta_i$.

The next step, given in Proposition 3.9, deduces sharp upper and lower bounds on the inverted orbit growth of $G_i$ on $X$. The first two steps together give sharp bounds on the growth of $W_\omega$, see Corollary 4.2.

For Theorem A, the last step is to construct, out of a function $f$ satisfying (1.1), a sequence $\omega$ such that $\eta_1 \ldots \eta_i$ grows appropriately in relation to $f$; see the precise statement in Lemma 5.3 and (5.4).

For Theorem B, the last step is to deduce, from expansion properties of the dynamical system on the 2-simplex, that the averages $(\eta_1 \ldots \eta_i)^{1/i}$ along periodic orbits of the dynamical system take a dense set of values in $[2, \eta_+]$. 

1.3. Prior work

In 1983, Grigorchuk proved the existence of groups with intermediate growth function between polynomial and exponential. This answered a long-standing question asked by Milnor [12]. Since then, the upper bound on the growth of Grigorchuk’s group has been improved to

$$v_{G_{012}} \lesssim \exp(R^{\alpha_-}) \approx \exp(R^{0.767}),$$

see [1]; and lower bounds of the form \(\exp(R^\beta)\) have been found, but for \(\beta\) substantially lower than \(\alpha_-\); see [25, 11, 2]. Note that previous literature often uses the notation \(\eta = 2/\eta_+\).

Grigorchuk constructed in [18, Theorem 7.2] a continuum of 2-groups \(G_\omega\) of intermediate growth, for \(\omega\) suitably chosen among infinite sequences over the alphabet \(\{0, 1, 2\}\). Similar constructions of \(p\)-groups for any prime \(p\), and of torsion-free groups were given in [19]. He proved that many \(G_\omega\) have nonequivalent growth functions, that their growth functions are not totally ordered, and that for every subexponentially growing function \(\rho\) there exists a group whose growth function \(v\) satisfies \(v \not\lesssim \rho\) and \(v \prec \exp(R)\). This argument was modified in [16] to show that for every such \(\rho\) there exists a group whose growth function satisfies \(\rho \prec v \prec \exp(R)\).

Grigorchuk’s argument was to consider the groups \(G_\omega\) for \(\omega\) containing very long subsequences of the form \(2^j\); he showed that the growth of \(G_\omega\) approaches the exponential function, at least on a subsequence. For these same sequences, we show that the growth of \(W_\omega\) uniformly approaches the exponential function.

At the other extreme, if \(\omega = 012\), the growth of \(G_\omega\) is minimal among the known superpolynomial growth functions.

Generally, good lower bounds for the growth of \(G_\omega\) seem much harder to construct than good upper bounds. On the one hand, there are combinatorial constructions of sufficiently many elements in the ball of radius \(R\), see [2, 25, 11]; probabilistic methods have also been used, see [14, 15].

A previous article by the authors [4] explores the growth of permutational wreath products of the form \(A \wr_X G := A^X \rtimes G\), for a group \(A\) and a group \(G\) acting on a set \(X\). They obtained in this manner groups of intermediate growth \(\sim \exp(R^\alpha)\) for a sequence of \(\alpha \rightarrow 1\); those were the first examples of groups of intermediate growth for which the growth function was determined. The method of proof is an estimation of the growth of “inverted orbits” of \(G\) on \(X\), see §3.2.
This construction was used by Brieussel [10], who gave for every \( \alpha \leq \beta \in (\alpha, 1) \) a group whose growth function oscillates between \( \exp(R^\alpha) \) and \( \exp(R^\beta) \) in the sense that \( \log \log v(n) / \log(n) \) accumulates both at \( \alpha \) and \( \beta \).

Kassabov and Pak [23] construct, for “sufficiently regular” functions \( v_{G_{012}} \preceq g_+ \preceq f_+ \preceq \exp(R) \), a group whose growth function is between \( g_- \) and \( f_+ \), and takes infinitely often values in \([f_-, f_+]\) and in \([g_-, g_+]\).

Until recently, the analogue of Theorem A wasn’t even known in the class of semigroups; though Trofimov shows in [29] that for any \( f_- \gtrsim R^2 \) and \( f_+ \gtrsim \exp(R) \) there exists a 2-generated semigroup with growth function infinitely often \( \leq f_- \) and infinitely often \( \geq f_+ \). For every submultiplicative function \( f \), a semigroup with growth between \( f(R) \) and \( Rf(R) \) is constructed in [7]. In particular, if \( f(CR) \geq Rf(R) \) for some \( C > 0 \) and all \( R \in \mathbb{N} \), then there exists a semigroup with growth \( \sim f \). In other words, all growth functions uniformly above \( R^{\log R} \) are realizable as the growth of a semigroup. Warfield showed in [30] that for every \( \beta \in [2, \infty) \) there exists a semigroup with growth \( \sim R^\beta \). The only known gap in growth functions of semigroups is Bergman’s, between linear and quadratic [24, Theorem 2.5].

1.4. Open problems

We would very much like to obtain a complete description of which equivalence classes of growth functions may occur as the growth of a group. Thanks to Gromov’s result [21] that groups of polynomial growth are virtually nilpotent and therefore of growth \( \sim n^d \) for an integer \( d \), we are interested in groups of intermediate growth. The groups that we construct have growth above \( \exp(R^{\alpha_-}) \). A tantalizing open problem in the existence of groups of growth between polynomial and \( \exp(\sqrt{n}) \); a conjecture of Grigorchuk asserts that they do not exist. It is not even known whether there are groups whose growth is strictly between polynomial and \( \exp(R^{\alpha_-}) \).

2. Self-similar groups

Self-similar groups are groups endowed with a self-similar action on sequences, namely, an action that is determined by actions on subsequences. We adopt a more algebraic notation.
Definition 2.1. — A self-similar group $G$ is a group endowed with a homomorphism $\phi : G \to G \wr \mathcal{S}_d$, for some $d \in \mathbb{N}$.

A self-similar group sequence is a sequence $(G_0, G_1, \ldots)$ of groups, with embeddings $\phi_i : G_i \to G_{i+1} \wr \mathcal{S}_{d_i}$ for all $i \in \mathbb{N}$.

A self-similar group gives rise to a self-similar group sequence: if $\phi : G \to G \wr \mathcal{S}_d$, then set $G_i = G$, $d_i = d$ and $\phi_i = \phi$ for all $i \in \mathbb{N}$.

Let $(G_i)$ be a self-similar group sequence, the $d_i$ and $\phi_i$ being implicit in the notation. Define

$$T_0 = \bigsqcup_{i \in \mathbb{N}} \{1, \ldots, d_0\} \times \cdots \times \{1, \ldots, d_{i-1}\}.$$ 

This is the vertex set of a rooted tree (with root the empty product $\emptyset$), if one puts an edge between $x_0 \cdots x_{i-1}$ and $x_0 \cdots x_{i-1}x_i$ for all $x_j \in \{1, \ldots, d_j\}$. We denote also this tree by $T_0$.

The group $G_0$ acts by isometries on $T_0$ as follows. Given $g \in G$ with $\phi_0(g) = (f, \pi)$ and $x_0 \cdots x_{i-1} \in T_0$, set

$$(x_0 \cdots x_{i-1})^g = \begin{cases} \emptyset & \text{if } i = 0, \\ (x_0^\pi)(x_1 \cdots x_{i-1})^f(x_0) & \text{inductively if } i > 0. \end{cases}$$

The boundary of $T_0$ is naturally identified with the set of infinite sequences

$$\partial T_0 = \prod_{i \in \mathbb{N}} \{1, \ldots, d_i\},$$

endowed with the product topology, and the action of $G$ on $T_0$ extends to a continuous action on $\partial T_0$.

Definition 2.2. — The self-similar group sequence $(G_i)$ is branched if there exist for all $i \in \mathbb{N}$ a finite-index subgroup $K_i \leq G_i$ such that $K_i^{d_i} \leq \phi_i(K_i)$ for all $i \in \mathbb{N}$.

For more information on branch groups, and the algebraic consequences that follow from that property, we refer to [6].

2.1. The Grigorchuk groups $G_\omega$

Our main examples were constructed by Grigorchuk in [18]. Let $\{0, 1, 2\}$ denote the three non-trivial homomorphisms from the four-group $\{1, b, c, d\}$ to the cyclic group $\{1, a\}$, ordered for definiteness by the condition that, in that order, they vanish on $b, c, d$ respectively. Write $\Omega = \{0, 1, 2\}^\mathbb{N}$ the space...
of infinite sequences over \( \{0, 1, 2\} \), endowed with the shift map \( s : \Omega \to \Omega \)
given by \( s(\omega_0 \omega_1 \cdots) = \omega_1 \omega_2 \cdots \).

Fix a sequence \( \omega \in \Omega \), and define a self-similar group sequence as follows. Take \( d = 2 \), and write \( \mathcal{G}_d = \{1, a\} \). Each \( G_i \) is generated by \( \{a, b, c, d\} \). Set
\[
\phi_i(a) = \langle\langle 1, 1\rangle\rangle a, \quad \phi_i(b) = \langle\langle \omega_i(b), b\rangle\rangle, \quad \phi_i(c) = \langle\langle \omega_i(c), c\rangle\rangle, \quad \phi_i(d) = \langle\langle \omega_i(d), d\rangle\rangle.
\]
The assertion that the \( \phi_i \) are homomorphisms, and that the \( G_i \) act faithfully
on the binary rooted tree, define the groups \( G_i \) uniquely.

Define the Grigorchuk group \( G_\omega \) as the group \( G_0 \) constructed above. We then have \( G_i = G_{s^i \omega} \) for all \( i \geq 0 \), so there are homomorphisms \( \phi_\omega : G_\omega \to G_{s^i \omega} \wr \mathcal{G}_2 \), and \( G_0 \) is the first entry of a self-similar group sequence.

If \( \omega \) is not ultimately constant, it is known that each of the \( G_\omega \) have intermediate growth, with growth bounded from below by \( \exp(R^{1/2}) \) and from above by \( \exp(R) \); and no smaller function may serve as upper bound [18], Theorem 7.1.

(This may be also seen concretely as follows: consider the “universal”
group \( \hat{G} \), defined as the diagonal subgroup generated by \( \hat{a} = (a, a, \ldots), \hat{b} = (b, b, \ldots), \hat{c} = (c, c, \ldots), \hat{d} = (d, d, \ldots) \) in \( \prod_{\omega \in \Omega} G_\omega \). Then this group has exponential growth — indeed, \( \{\hat{a} \hat{b}, \hat{a} \hat{c}, \hat{a} \hat{d}\} \) freely generates a free semigroup.)

**Proposition 2.3.** — The group \( G_\omega \) is the first term of a self-similar
group sequence:

1. if \( \omega \) contains only a finite number of one of the three symbols, then \( G_\omega \) contains an element of infinite order;
2. if the sequence \( \omega \) contains infinitely many of each of the three symbols, then \( G_\omega \) is an infinite, branched, torsion group;
3. if \( \omega \) is periodic and contains each of the three symbols \( 0, 1, 2 \), then \( G_\omega \) is also self-similar.

**Proof.** — It was already proven in [18] that \( G_\omega \) is torsion if and only if \( \omega \) contains all three symbols.

To show that \( G_\omega \) are branched, consider the groups \( G_i = G_{s^i \omega} \) and homomorphisms \( \phi_i : G_i \to G_{i+1} \wr \mathcal{G}_2 \). For each \( i \in \mathbb{N} \), let \( x_i \in \{b, c, d\} \) be such that \( \omega_i(x_i) = 1 \), and set \( K_i = \langle \langle [x_i, a] \rangle \rangle^{G_i} \). Choose also \( y_i \in \{b, c, d\} \setminus \{x_i\} \). Then \( 1 \times K_{i+1} \) is normally generated by \( \langle \langle 1, [x_{i+1}, a] \rangle \rangle \), and
\[
\langle \langle 1, [x_{i+1}, a] \rangle \rangle = \phi_i([x_i, y_i]) = \phi_i([x_i, a][x_i, a]^{a^i}) \in \phi_i(K_i);
\]
the same holds for \( \langle \langle [x_{i+1}, a], 1 \rangle \rangle \).

Consider first \( G_i/\langle x_i \rangle^{G_i} \). This group is generated by two involutions \( a \) and \( y_i \), so is a finite dihedral group, because \( G_i \) is torsion. It follows that
\( \langle x_i \rangle^{G_i} \) has finite index in \( G_i \). Then \( \langle x_i \rangle^{G_i} / K_i = \langle x_i \rangle K_i \) has order 2, so \( K_i \) also has finite index.

Finally, if \( \omega \) is periodic, say of period \( n \), then \( G_0 = G_n \) and the composition of the maps \( \phi_i \) gives a homomorphism \( \phi : G_0 \to G_0 \wr \mathfrak{S}_{2^n} \), showing that \( G_\omega \) is self-similar. \[\Box\]

2.2. The Groups \( W_\omega \)

Fix a finitely generated group \( A \), an infinite sequence \( \rho \in \{1, 2\}^\infty \) such as for example \( \rho = 2^\infty \), and its orbit \( X := \rho \cdot G_\omega \). Consider \( W_\omega := A \wr_X G_\omega \).

**Proposition 2.4.** — The group \( W_\omega \) is finitely generated, and is the first term of a branched self-similar group sequence.

If \( \omega \) and \( \rho \) are periodic, then \( W_\omega \) is also self-similar.

If \( \omega \) and \( \rho \) are recursive and \( A \) is recursively presented, then so is \( W_\omega \). If moreover \( A \) has a solvable word problem, then so does \( W_\omega \).

If \( A \) is torsion and \( \omega \) contains infinitely many of all three symbols, then \( W_\omega \) is torsion.

**Proof.** — Clearly \( W_\omega \) is generated by \( \{a, b, c, d\} \cup S \) for a finite generating set \( S \) of \( A \); we imbed \( A \) in \( W_\omega \) as those functions \( X \to A \) supported on \( \{\rho\} \).

Let \( (G_i) \) be the self-similar group sequence with \( G_0 = G_\omega \). Let \( \rho_i \) be the subsequence of \( \rho \) starting at position \( i \). Define \( W_i := A \wr_{\rho_i} G_i \), with imbeddings \( \psi_i : W_i \to W_{i+1} \wr \mathfrak{S}_2 \) given as follows. Consider \( w = (u, g) \in W_i \), with \( u : \rho_i G \to A \) and \( g \in G_i \). Write \( \phi_i(g) = (f, \pi) \) with \( f : \{1, 2\} \to G_{i+1} \) and \( \pi \in \mathfrak{S}_2 \). For \( k \in \{1, 2\} \), set \( u_k(x) := u(kx) : \rho_{i+1} G_{i+1} \to A \). Then

\[
\psi_i(u, g) = (k \mapsto (u_k, f(k), \pi)).
\]

Furthermore, let \( K_i \) be the finite-index subgroup of \( G_i \) for which \( (G_i) \) is branched. Then \( L_i := A \wr K_i \) has finite index in \( W_i \), and shows that \( (W_i) \) is branched.

If \( \omega \) is periodic, say of period \( n \), then \( G_0 = G_n \) and we get, composing the maps \( \phi_0, \ldots, \phi_{n-1} \), an imbedding \( \phi : G_0 \to G_0 \wr \mathfrak{S}_{2^n} \), showing that \( G_\omega \) is self-similar. The same holds for \( W_\omega \).

For a presentation of \( W_\omega \), see \[3\], \[13\] and \[4\]. Let \( A \) be generated by a finite set \( S \); then \( W_\omega \) is generated by \( S \cup \{a, b, c, d\} \). The relations of \( W_\omega \) are the following: those of \( A \); those of \( G_\omega \); commutation relations \( [s, (s')^\rho] \) for all \( s, s' \in S \) and \( g \in G_\omega \) not fixing \( \rho \); and commutation relations \( [s, g] \) for all \( s \in S \) and \( g \in G_\omega \) fixing \( \rho \).
If \( \omega \) is recursive, then the action of \( G_\omega \) on \( X \) is computable, so the sets 
\[
\{ w \in \{a, b, c, d\}^* \mid \rho w = w \} \quad \text{and} \quad \{ w \in \{a, b, c, d\}^* \mid \rho w \neq w \}
\]
are recursive; so \( W_\omega \) is recursively presented.

If moreover the word problem is solvable in \( A \), then it is also solvable in \( W_\omega \). Indeed \( G_\omega \) is contracting, so the word problem is solvable in \( G_\omega \); see §2.4. A word in \( W_\omega \) is trivial if and only if its image in \( G_\omega \) is trivial and its values at all \( x \in X \) are trivial in \( A \).

If \( \omega \) contains infinitely many of all three symbols, then \( G_\omega \) is torsion; if moreover \( A \) is torsion, then \( W_\omega \), being an extension of two torsion groups, is also torsion.

\[\square\]

2.3. The torsion-free groups \( \tilde{G}_\omega \)

Grigorchuk constructed in [19, §5] a torsion-free group \( \tilde{G} \) of intermediate growth; it was later noted in [20] that \( \tilde{G} \) acts continuously on the interval \([0,1]\). We shall consider variants \( \tilde{G}_\omega \) of his construction, which we now recall.

The group \( \tilde{G}_\omega \) is the first term of a self-similar group sequence in the sense of Definition 2.1, but the map \( \phi : \tilde{G}_\omega \to \tilde{G}_{s_\omega} \wr \mathbb{S}_2 \) is not injective. We construct the groups \( \tilde{G}_\omega \) via a slightly different definition. Each of the groups \( \tilde{G}_\omega \) acts faithfully on the rooted tree of infinite degree, whose vertex set is naturally identified with finite sequences over \( \mathbb{Z} \), and whose boundary is naturally the space \( \mathbb{Z}^\infty \) of infinite sequences of integers. Each \( \tilde{G}_\omega \) is generated by \( \{a, b, c, d\} \). Each \( \omega \in \{0, 1, 2\} \) is now understood as a homomorphism \( \langle b, c, d \rangle \iso \mathbb{Z} \to \langle a \rangle \iso \mathbb{Z} \), via \( 0(b) = 1, 0(c) = 0(d) = a \) etc. under cyclic permutation. There is a homomorphism \( \tilde{\phi}_\omega : \tilde{G}_\omega \to \prod \mathbb{Z} \tilde{G}_\omega \times \mathbb{Z} \), given by

\[
\tilde{\phi}_\omega(a) = \langle \ldots, 1, 1, \ldots \rangle (n \mapsto n + 1),
\]

\[
\tilde{\phi}_\omega(x) = \langle \ldots, \omega_0(x), x, \ldots \rangle \quad \text{for all} \quad x \in \{b, c, d\},
\]

where the \( \ldots \) indicate that the sequence repeats 2-periodically. In particular, the map \( a \mapsto a, b \mapsto b, c \mapsto c, d \mapsto d \) extends to an epimorphism \( \xi_\omega : \tilde{G}_\omega \to G_\omega \).

The kernel of \( \xi_{012} \) is abelian, isomorphic to \( \mathbb{Z} \times \sum_X \mathbb{Z}^3 \); this is essentially due to Grigorchuk, see [4, Lemma 5.7] for a proof. Note then that the argument extends with no changes to ker \( \xi_\omega \) for arbitrary \( \omega \). We proved in [4, Proposition 5.8] that \( \tilde{G}_{012} \) has growth function equivalent to \( \mathbb{Z}^3 \wr G_{012} \); again, the argument extends without changes to all \( \tilde{G}_\omega \).
The following result essentially appears in [20]; there, Grigorchuk and Macki show that \( \tilde{G}_{\Omega} \) is residually virtually nilpotent and residually solvable.

**Lemma 2.5.** — The group \( \tilde{G}_{\omega} \) is residually 2-finite.

**Proof.** — For all \( n \in \mathbb{N} \), let \( \pi_n \) denote the homomorphism \( G_{\omega} \to S_{2^n} \) defined by restricting the action of \( G_{\omega} \) to sequences in \( \{1, 2\}^n \), and let \( N_n \) be the normal closure in \( \tilde{G}_{\omega} \) of \( \langle a^{2^n}, b^{2^n}, c^{2^n}, d^{2^n} \rangle \).

Consider then the normal subgroups \( P_n = N_n \ker(\pi_n \circ \xi_{\omega}) \) of \( \tilde{G}_{\omega} \). On the one hand, \( \tilde{G}_{\omega}/P_n \) is a finite 2-group: it is a torsion abelian 2-extension of the finite 2-group \( \pi_n(G_{\omega}) \). On the other hand, \( P_\infty := \bigcap_{n \in \mathbb{N}} P_n \) is trivial: \( P_\infty \) is contained in \( \ker \xi_{\omega} \cong \mathbb{Z} \times \sum_X \mathbb{Z}^3 \), and is 2-divisible in \( \tilde{G}_{\omega} \). \( \square \)

### 2.4. Presentations

Assume that \( \omega \) is a recursive sequence; that is, there is an algorithm that, given \( n \in \mathbb{N} \) as input, computes the \( n \)th letter of \( \omega \). We then claim that \( G_{\omega} \) and \( \tilde{G}_{\omega} \) have solvable word problem; that is, there are algorithms that, given a word \( w \in \{a, b, c, d\}^* \) as input, compute whether \( w = 1 \) in \( G_{\omega} \) and whether \( w = 1 \) in \( \tilde{G}_{\omega} \).

Indeed, the following algorithm solves the word problem in \( G_{\omega} \). Given \( w \in \{a, b, c, d\}^* \), first perform all elementary cancellations \( a^2 \to 1, b^2 \to 1, \ldots, bc \to d, \ldots \). If \( w \) became the empty word, then \( w = 1 \) in \( G_{\omega} \). Otherwise, if the exponent sum of \( a \) in \( w \) is non-zero, then \( w \neq 1 \) in \( G_{\omega} \). Otherwise, compute \( \omega_0 \), and using it compute \( \phi_0(w) = \langle \langle w_1, w_2 \rangle \rangle \). Noting that \( s_\omega \) is again a recursive sequence, apply the algorithm recursively to \( w_1 \) and \( w_2 \), to determine whether both are trivial in \( G_{s_\omega} \).

The algorithm terminates because \( G_{\omega} \) is contracting.

A small modification of that algorithm solves the word problem in \( \tilde{G}_{\omega} \). Given \( w \in \{a^{\pm 1}, b^{\pm 1}, c^{\pm 1}, d^{\pm 1}\}^* \), first perform all elementary substitutions \( cb \to bc, dc \to cd, db \to bd \) and free cancellations. If \( w \) became the empty word, then \( w = 1 \) in \( \tilde{G}_{\omega} \). Otherwise, if the exponent sum of \( a \) in \( w \) is non-zero, or if \( w \in \langle b, c, d \rangle \), then \( w \neq 1 \) in \( \tilde{G}_{\omega} \). Otherwise, compute \( \omega_0 \), and using it compute \( \tilde{\phi}_0(w) = \langle \langle w_1, w_2 \rangle \rangle \). Noting that \( s_\omega \) is again a recursive sequence, apply the algorithm recursively to \( w_1 \) and \( w_2 \), to determine whether both are trivial in \( \tilde{G}_{s_\omega} \).

**Corollary 2.6.** — If \( \omega \) is recursive, then \( G_{\omega} \) and \( \tilde{G}_{\omega} \) have solvable word problem, and are recursively presented.
Proof. — The solution of the word problem is given by the algorithms above. The groups are then recursively presented, by taking as relators, e.g., all words that are trivial in them. □

More efficient recursive presentations are described in [28].

Note that (unless $\omega$ is eventually constant) the group $G_{\omega}$ is not finitely presented. In fact, no finitely presented example of branched group with injective $\phi$ is known.

On the other hand, contracting groups may be described by a finite amount of data, and this immediately implies that there are countably many such groups. Let $G$ be a contracting group, with self-similarity map $\phi : G \hookrightarrow G \wr S_d$. Fix the notation $\phi(g) = \langle \langle g_1, \ldots, g_d \rangle \rangle \pi_g$. The contracting property implies that there are constants $\lambda < 1$ and $C$ such that $\|g_i\| \leq \lambda \|g\| + C$.

Fix a generating set $S$ for $G$. The map $\phi$ is determined by its values on generators, namely by $\# S$ permutations in $\mathfrak{S}_d$ and $d \# S$ words in the free group on $S$. The corresponding map $\phi : F_S \to F_S \wr \mathfrak{S}_d$ is not contracting, but there exists a finitely presented quotient $\hat{G}$ of $F_S$, with $F_S \to \hat{G} \to G$, for which the induced map $\phi : \hat{G} \to \hat{G} \wr \mathfrak{S}_d$ is contracting (but not injective).

The contraction property implies the following: for any $g \in \hat{G}$, sufficiently many applications of $\phi$ and projection to a coordinate $g_i$ result in elements of norm at most $B := (C + 1)/(1 - \lambda)$. There are finitely many elements in the ball of radius $B$ in $\hat{G}$; let us fix which of these elements project to the identity in $G$.

We claim that these data — the map $\phi : S \to F_S \wr \mathfrak{S}_d$, the finitely presented group $\hat{G}$, and the set $W$ of words of length less than $B$ in $G$ projecting to the identity in $G$ — determine $G$ completely. To see that, it is sufficient to exhibit an algorithm solving the word problem in $G$.

Given $g \in G$, written as a word in $S$, do the following. If $\|g\| < B$, then $g = 1$ if and only if it belongs to $W$. Otherwise, compute $\phi(g) = \langle \langle g_1, \ldots, g_d \rangle \rangle \pi_g$. If $\pi_g \neq 1$, then $g \neq 1$. Otherwise, apply recursively the algorithm to determine whether $g_1, \ldots, g_d$ are all trivial in $G$. This is well-founded because (by the contraction property) we have $\|g_i\| \leq \|g\| - 1$.

3. Metrics on the Grigorchuk groups $G_{\omega}$

Let $G_{\omega}$ be a Grigorchuk group as above; it is the first entry of a self-similar group sequence with $G_i = G_{s_i \omega}$. We put a word metric on each $G_i$, i.e. a metric $\| \cdot \|_i$ defined by assigning a norm to each generator and
extending it naturally to group elements. This metric is determined by a point $V_i$ in the open simplex

$$\Delta = \left\{ (\beta, \gamma, \delta) \mid \max\{\beta, \gamma, \delta\} < \frac{1}{2}, \beta + \gamma + \delta = 1 \right\}$$

with vertices $(\frac{1}{2}, \frac{1}{2}, 0), (\frac{1}{2}, 0, \frac{1}{2}), (0, \frac{1}{2}, \frac{1}{2})$. It assigns norm $\alpha := 1 - 2 \max\{\beta, \gamma, \delta\}$ to $a$, and norms $\beta - \alpha, \gamma - \alpha, \delta - \alpha$ to $b, c, d$ respectively.

In particular, the norm of the longest of $b, c, d$ equals the sum of the norms of the two shortest.

In order to appropriately construct metrics on the $G_i$, we consider the space $\Delta \times \Omega$, and define three $3 \times 3$ matrices $M_x$, for $x \in \{0, 1, 2\}$, by

$$M_0 = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{pmatrix}, M_1 = \begin{pmatrix} 2 & 0 & 0 \\ 1 & 1 & 1 \\ 0 & 0 & 2 \end{pmatrix}, M_2 = \begin{pmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 1 & 1 & 1 \end{pmatrix}.$$ 

(3.1)

Define a continuous function $\eta: \Delta \times \{0, 1, 2\} \to (2, 3]$ by the condition $\eta(p, x)^{-1} M_x(p) \in \Delta$, and projective maps $\overline{M}_x: \Delta \to \Delta$ by the $\overline{M}_x(p, x) = \eta(p, x)^{-1} M_x(p)$. Define next a shift map $s: \Delta \times \Omega \to \Delta \times \Omega$ by

$$s(p, \omega_0\omega_1\ldots) = (\overline{M}_{\omega_0}(p), \omega_1\omega_2\ldots).$$

Define finally a continuous function $\mu: \Delta \to (0, \frac{1}{2}]$ by

$$\mu(\beta, \gamma, \delta) = \min\{\beta, \gamma, \delta\}.$$ 

The function $\mu(p)$ is equivalent to the minimal euclidean distance from $p \in \Delta$ to a vertex of $\Delta$.

Note that the $\overline{M}_x$ have disjoint images, and that the union of their images is dense in $\Delta$. More precisely, each $\overline{M}_x$ maps $\Delta$ to the simplex spanned by two vertices and the barycentre of $\Delta$. The shift map $s: \Delta \times \Omega \to \Delta \times \Omega$ is injective with dense image. Define $\Delta' \subset \Delta$ by

$$\Omega^+ = \bigcap_{k \geq 0} s^k(\Delta \times \Omega) = \Delta' \times \Omega.$$ 

Then $\Delta'$ is dense in $\Delta$, being the complement of countably many line segments, and $s: \Omega^+ \to \Omega^+$ is bijective. The metric on $G_i$ determined by $p \in \Delta'$ is non-degenerate.

Endow $\Delta$ with the Hilbert metric $d_\Delta(V_1, V_2) = \log(V_1, V_2; V_-, V_+)$, computed using the cross-ratio of the points $V_1, V_2$ and the intersections $V_-, V_+$ of the line containing $V_1, V_2$ with the boundary of $\Delta$. Endow $\Omega$ with the Bernoulli metric $d(\omega, \omega') = \sum_{i: \omega_i \neq \omega'_i} 2^{-i}$.

**Lemma 3.1** (Essentially [9]; we have not been able to locate a proof of the following extension). — **Let $K$ be a convex subset of a real vector**
space, and let \( A : K \rightarrow K \) be a projective map. Then \( A \) is 1-Lipschitz for the Hilbert metric.

If furthermore \( A(K) \) contains no lines from \( K \) (that is, \( A(K) \cap \ell \neq K \cap \ell \) for every line \( \ell \) intersecting \( K \)), then \( A \) is strictly contracting.

Proof. — Since \( A \) is projective, it preserves the cross-ratio on lines, so we have \( d_{A(K)}(A(V_1), A(V_2)) = d_K(V_1, V_2) \) for all \( V_1, V_2 \in K \). Furthermore, on the line \( \ell \) through \( V_1, V_2 \), the intersection points \( \ell \cap \partial A(K) \) are not further from \( V_1, V_2 \) than \( \{ V_+, V_- \} = \ell \cap \partial K \); the Hilbert metric decreases as \( V_+ \) are moved apart from \( V_1, V_2 \), and this gives strict contraction under the condition \( A(K) \cap \ell \neq K \cap \ell \).

Lemma 3.2. — The homeomorphism \( s : \Omega^+ \rightarrow \Omega^+ \) is ‘hyperbolic’: it decomposes as the product of an expanding and contracting map.

Proof. — The expanding direction is \( \Omega \); indeed the Bernoulli metric is doubled by the shift map. The contracting direction is \( \Delta \); indeed the maps \( \overline{M}_x \) are projective, hence contracting by Lemma 3.1. Note that the contraction is strict, but not uniform.

Let \( V_0 \in \Delta' \) be a given metric on \( G_\omega \); this defines a point \( (V_0, \omega) \in \Omega^+ \). We then let \( V_i \) be the first coordinate of \( s^i(V_0, \omega) \), and have defined a metric \( \| \cdot \|_{\Omega} \) on each \( G_i \). We also set \( \eta_i = \eta(V_i, \omega_i) \) and \( \mu_i = \mu(V_i) \), to lighten notation.

(Note that the choice of \( V_0 \in \Delta' \) will ultimately not be very important, because the maps \( \overline{M}_x \) are contracting. Indeed, for two choices \( V_0, V_0' \) we have \( V_i \rightarrow V_i' \), so \( \mu_i \rightarrow \mu_i' \) and \( \eta_i \rightarrow \eta' \) as \( i \rightarrow \infty \).)

Lemma 3.3. — For each \( i \geq 0 \) and each \( g \in G_i \), with \( \phi_i(g) = \langle \langle g_1, g_2 \rangle \rangle \pi \), we have

\[
\| g_1 \|_{\Omega} + \| g_2 \|_{\Omega} + 1 \leq \frac{2}{\eta_i} (\| g \|_{\Omega} + \| a \|_{\Omega})
\]

Proof. — We consider first \( \omega_i = 0 \); the general case will follow. Consider \( V_i = (\beta_i, \gamma_i, \delta_i) \in \Delta \), and \( V_{i+1} = \overline{M}_0(V_i) = (\beta_{i+1}, \gamma_{i+1}, \delta_{i+1}) \). We compute \( \eta_i = \eta(V_i, 0) = 3 - 2\beta_i \), and \( V_{i+1} = (1/\eta_i, 2\gamma/\eta_i, 2\delta/\eta_i) \), so

\[
\| b \|_{\Omega} + 1 = \beta_{i+1} - \| a \|_{\Omega} = \beta_{i+1} - 1 + 2\beta_{i+1} = 3/\eta_i - 1 = 2\beta_i/\eta_i.
\]

The same result holds, cyclically permuting \( \beta, \gamma, \delta \), for all \( \overline{M}_x \). We therefore have

\[
\| b \|_{\Omega} + 1 + \omega_i(b) \|_{\Omega} + 1 = 2\beta_i/\eta_i = 2/\eta_i(\| b \|_{\Omega} + \| a \|_{\Omega}),
\]

(3.2)

\[
\| c \|_{\Omega} + 1 + \omega_i(c) \|_{\Omega} + 1 = 2\gamma_i/\eta_i = 2/\eta_i(\| c \|_{\Omega} + \| a \|_{\Omega}),
\]

\[
\| d \|_{\Omega} + 1 + \omega_i(d) \|_{\Omega} + 1 = 2\delta_i/\eta_i = 2/\eta_i(\| d \|_{\Omega} + \| a \|_{\Omega}).
\]
On the other hand, \( g \) may be written as an alternating word in \( a \) and \( b, c, d \), because of the relations \( b^2 = c^2 = d^2 = bcd = 1 \). Group each \( b, c, d \)-letter with an \( a \), and sum the corresponding inequalities; there may be an \( a \) left over. This gives the desired inequality. 

Even though the metrics we consider on \( G_\omega \) are not word metrics, the volume of small balls are well understood. We include the following result for future reference, though it will not be used in this article:

**Lemma 3.4.** — There are two absolute constants \( K_1, K_2 > 0 \) such that, for every group \( G_\omega \) with metric given by \( V_0 \in \Delta \), we have

\[
\frac{K_1}{\mu_0} \leq v(1/2) \leq \frac{K_2}{\mu_0}.
\]

**Proof.** — Assume without loss of generality \( \beta \leq \gamma \leq \delta \). A word of norm \( \leq \beta \) and length \( \geq 4 \) may contain only as and bs, because otherwise it would have norm at least \( \beta + \gamma > 1 \). It must therefore be of the form \( b^i(ab)^ja^k \) for \( i, k \in \{0, 1\} \) and \( 0 \leq j \leq \beta^{-1} \).

**Lemma 3.5.** — For every \( A > 0 \) there exists a constant \( K \), such that, for all \( V_0 \in \Delta' \), we have \( v(A\mu_0) \leq K \).

**Proof.** — The minimal norm in \( (G_\omega, \| \cdot \|_{V_0}) \) of a non-trivial product of two generators is \( \mu_0 \); we can therefore take \( K = 4^{2A} \).

### 3.1. Volume growth of \( G_\omega \), upper bound

Let \( v_i(R) \) denote the volume growth of \( G_i \) for the metric \( \| \cdot \|_i \). The following proposition, and its variants in §3.2, are key to our computation of growth functions.

**Proposition 3.6.** — There is an absolute constant \( B \) such that for all \( k \in \mathbb{N} \), we have

\[
v_0(\eta_0\eta_1\cdots\eta_{k-1}\mu_k) \leq B^{2^k}.
\]

Before embarking in the proof, we give a few preliminary definitions and results. For a non-negative function \( f(R) \), its **concave majorand** is the smallest concave function \( f^+ \) greater than \( f \); the graph of \( f^+ \) bounds the convex hull of the graph of \( f \). It may be defined by

\[
f^+(R) = \sup_{p<R<q} \left( \frac{q-R}{q-p} f(p) + \frac{R-p}{q-p} f(q) \right).
\]

(3.3)

The following lemma is not used in the argument, but only included for illustration. It implies that the growth functions considered in Theorem A are equivalent to log-concave functions.
Lemma 3.7. — Let $g: \mathbb{R} \to \mathbb{R}$ be a function satisfying

$$g(2R) \leq 2g(R) \leq g(\eta + R)$$

for all $R$ large enough. Then $g$ is equivalent to a concave function.

Proof. — First, the inequality $g(2R) \leq g(R)$ alone implies that $g$ is equivalent to a subadditive function, namely a function satisfying $g(R + S) \leq g(R) + g(S)$. We therefore assume, without loss of generality, that $g$ is subadditive. Let $g^*$ be the concave majorand of $g$, as in (3.3). We will show $g^* \leq 2g$; this with the second inequality in (3.4) yields the claim.

Without loss of generality, assume also that $g$ is increasing. Consider $a < x < b$ such that $g^*(x) = (x - a)/(b - a)g(b) + (b - x)/(b - a)g(a)$. Write $b = Nx + c$ with $0 \leq c < x$. Then

$$\begin{align*}
(b - a)g^*(x) &= (x - a)g(Nx + c) + ((N - 1)x + c)g(a) \\
&\leq (x - a)(Ng(x) + g(c)) + ((N - 1)x + c)g(a) \\
&\leq (x - a)(N + 1)g(x) + ((N - 1)x + c)g(x) \\
&= (2Nx + c - (N + 1)a)g(x) \\
&\leq 2(b - a)g(x),
\end{align*}$$

so $g^*(x) \leq 2g(x)$. \hfill \Box

Lemma 3.8. — For all $k \in \mathbb{N}$ we have $\eta_k \mu_{k+1} \geq \mu_k + \|a\|_k$.

Proof. — We write $V_k = (\beta, \gamma, \delta)$, and assume without loss of generality $\omega_k = 0$. Then the inequality

$$\eta_k \mu_{k+1} = 2 \min \{\gamma, \delta\} \geq \min \{\beta, \gamma, \delta\} + (1 - \max \{\beta, \gamma, \delta\}) = \mu_k + \|a\|_k$$

is checked by considering the six cases $\beta < \gamma < \delta$ etc. in turn. \hfill \Box

Proof of Proposition 3.6. — We derive a relation between $v_i$ and $v_{i+1}$ from Lemma 3.3. The integrals $\int_{p_1 + p_2 = K}$ are really finite sums, because their arguments are piecewise constant; however, in these finite sums the parameters $p_1, p_2$ do not take integral values. We have:

$$v_i(R) \leq \int_{p_1 + p_2 = 2/\eta_i(R + \|a\|_i)} 2v_{i+1}(p_1)v_{i+1}(p_2)$$

$$\leq 2 \left( 1 + \frac{2}{\eta_i(R + \|a\|_i)} \right) \max_{p_1 + p_2 = 2/\eta_i(R + \|a\|_i)} v_{i+1}(p_1)v_{i+1}(p_2).$$
Set $\alpha_i(R) := (\log v_i)^+(R)$. Below, we abbreviate in “…” the development of $\log v_i(q)$, which is similar to that of $\log v_i(p)$:

$$
\alpha_i(R) = \sup_{p < R < q} \left\{ \frac{q - R}{q - p} \log v_i(p) + \frac{R - p}{q - p} \log v_i(q) \right\}
\leq \sup_{p < R < q} \left\{ \frac{q - R}{q - p} \log \int_{p_1 + p_2 = \frac{2}{\eta_i} (p + \|a\|)} (p_1) v_{i+1}(p_2) + \frac{R - p}{q - p} \cdots \right\}
\leq \log 2 + \sup_{p < R < q} \left\{ \frac{q - R}{q - p} \log \int_{p_1 + p_2 = \frac{2}{\eta_i} (p + \|a\|)} \exp(\alpha_{i+1}(p_1) + \alpha_{i+1}(p_2)) + \frac{R - p}{q - p} \cdots \right\}
\leq \log 2 + \sup_{p < R < q} \left\{ \frac{q - R}{q - p} \log \int_{p_1 + p_2 = \frac{2}{\eta_i} (p + \|a\|)} \exp(2\alpha_{i+1}(\frac{p + \|a\|}{\eta_i})) + \frac{R - p}{q - p} \cdots \right\}
\leq \log 2 + \sup_{p < R < q} \left\{ \frac{q - R}{q - p} \log \left( 1 + 2\left(\frac{p + \|a\|}{\eta_i}\right)\right) + 2\alpha_{i+1}(\frac{p + \|a\|}{\eta_i}) + \frac{R - p}{q - p} \cdots \right\}
\leq \log 2 + \log \left( 1 + 2\left(\frac{R + \|a\|}{\eta_i}\right)\right) + 2\alpha_{i+1}(\frac{R + \|a\|}{\eta_i})
$$

because $\alpha_{i+1}$ and $\log(1 + \cdots)$ are concave.

Set then $\beta_i(R) = \alpha_i(R + \mu_i) + \log(1 + R + \mu_i) + 2 \log 2 + 2 \log 3$. We will in fact prove the stronger inequality $\beta_0(\eta_0 \eta_1 \cdots \eta_{k-1} \mu_k) \leq 2^k B'$ for an absolute constant $B'$. We have

$$
\beta_i(R) = \alpha_i(R + \mu_i) + \log(1 + R + \mu_i) + 2 \log 2 + 2 \log 3
\leq 3 \log 2 + 2 \log 3 + \log(1 + R + \mu_i) + \log \left( 1 + \frac{2(R + \|a\|)}{\eta_i} \right) + 2\alpha_{i+1}(\frac{R + \mu_i + \|a\|}{\eta_i})
$$
\[
\leq 2 \left(2 \log 2 + \log \eta_i + \log \left(1 + \frac{R}{\eta_i} + \mu_{i+1}\right) + \alpha_{i+1} \left(\frac{R}{\eta_i} + \mu_{i+1}\right)\right) \text{ by Lemma 3.8}
\]
\[
\leq 2\beta_{i+1}(R/\eta_i).
\]
We therefore have
\[
\alpha_0(\eta_0 \cdots \eta_k \mu_k) \leq \beta_0(\eta_0 \cdots \eta_{k-1} \mu_k) \leq 2^k \beta_k(\mu_k) \leq \alpha_k(2\mu_k) + \log(1 + 2\mu_k) + \log 36,
\]
and \(\alpha_k(2\mu_k)\) is bounded by Lemma 3.5. \(\square\)

### 3.2. Inverted orbit growth of \(G_\omega\)

Recall that, for a group \(G\) acting on a set \(X\) on the right and a basepoint \(* \in X\), and for a word \(w = g_1 \cdots g_R \in G^*\), we denote by \(\Delta(w)\) the cardinality of the inverted orbit \(\{*g_1 \cdots g_R, *g_2 \cdots g_R, \ldots, *g_R, *\}\) of \(*\) under \(w\). We denote by \(\Delta(R)\) the maximal inverted orbit growth of words \(w \in S^R\). Following the notation used before, we denote by \(\Delta_i(R)\) the maximal size of an inverted orbit under a word in \(G_i\) of norm at most \(R\) in the metric \(\| \cdot \|_i\).

**Proposition 3.9.** — There is an absolute constant \(C\) such that for all \(k \in \mathbb{N}\) we have
\[
2^k \leq \Delta(\eta_0 \cdots \eta_{k-1} \mu_k) \leq C 2^k.
\]

**Proof of the upper bound.** — The calculation in this section follows closely that of the previous §. Let again \(\Delta_i^+\) denote the concave majorand of \(\Delta_i\). Lemma 3.3 gives
\[
\Delta_i^+(\eta_i R) \leq 2 \Delta_{i+1}(R + \|a\|_i/\eta_i).
\]
The same argument as above applies, and we do not repeat it. \(\square\)

On the other hand, we also obtain a lower bound on the inverted orbit growth, using a substitution. For that purpose, define self-substitutions \(\zeta_x\) of \(\{ab, ac, ad\}\), for \(x \in \{0, 1, 2\}\), by
\[
\zeta_0 : \quad \begin{align*}
ab &\mapsto adabac, &
ac &\mapsto acac, &
\quad ad &\mapsto adad, \\
\zeta_1 : \quad \begin{align*}
ab &\mapsto abab, &
ac &\mapsto abacad, &
\quad ad &\mapsto adad, \\
\zeta_2 : \quad \begin{align*}
ab &\mapsto abab, &
ac &\mapsto acac, &
\quad ad &\mapsto acadab,
\end{align*}
\end{align*}
\]
and note that, for any word \( w \in \{ab, ac, ad\}^\ast \) (representing an element of \( G_{i+1} \)) we have

\[
\phi_i(\zeta_i(w)) \begin{cases} 
\langle \langle w, w \rangle \rangle & \text{if } \zeta_i(w) \text{ contains an even number of } 'a' \\
\varepsilon \langle \langle wa, a^{-1}w \rangle \rangle & \text{if } \zeta_i(w) \text{ contains an odd number of } 'a'.
\end{cases}
\]

In particular, \( \zeta_x \) defines a homomorphism \( G_{i+1} \to G_i \).

**Proof of the lower bound.** — By induction, we see that for any non-trivial \( w \in \{ab, ac, ad\}^\ast \) (representing an element of \( G_k \)) we have

\[
\Delta_0(\zeta_{\omega_0} \cdots \zeta_{\omega_{k-1}}(w)) \geq 2^k.
\]

Note then that, if \( Z \in \mathbb{N}^3 \) count the numbers of \( ab, ac, ad \) respectively in \( w \), then \( Z^tM_x \) counts the numbers of \( ab, ac, ad \) respectively in \( \zeta_x(w) \). Let \( as \in \{ab, ac, ad\} \) be such that \( \|s\|_k \) is minimal — if \( \beta < \gamma, \delta \) then \( s = b \), etc. Let \( W \) be the vector in \( \mathbb{R}^3 \) with a 1 at the position which \( s \) has in \( \{ab, ac, ad\} \) and 0 elsewhere — if \( \beta < \gamma, \delta \) then \( W = (1, 0, 0)^t \), etc. Set \( w = \zeta_{\omega_0} \cdots \zeta_{\omega_{k-1}}(s) \). We have \( \Delta_0(w) \geq 2^k \), and

\[
\|w\|_0 = W^t M_{\omega_{k-1}} \cdots M_{\omega_0} V_0 = \eta_0 \cdots \eta_{k-1} W^t V_k = \eta_0 \cdots \eta_{k-1} \mu_k.
\]

\[
\square
\]

### 3.3. Choice of inverted orbits growth

If \( w \) be a word of norm \( R \) over \( G \), then its inverted orbit \( O_w \) is a subset of \( X \) of cardinality at most \( R + 1 \), and containing *. Furthermore, if \( w \) is a word over \( S \), then \( O_w \) is contained in the ball of radius \( R \) in the Schreier graph of \( (X, *) \). The set \( \{O_w \mid w \in S^R\} \) is therefore a finite subset of the power set of \( X \), and we denote its cardinality by \( \Sigma(R) \).

**Proposition 3.10.** — *There is an absolute constant \( D \) such that for all \( k \in \mathbb{N} \) we have

\[
\Sigma(\eta_0 \cdots \eta_{k-1} \mu_k) \leq D^{2^k}.
\]

**Proof.** — Again we denote by \( \Sigma_i(R) \) the choice of inverted orbits growth function of \( G_i \). The relevant inequality is

\[
\Sigma_i(\eta R) \leq \int_{\ell+m=R+\|a\|_i/\eta_i} \Sigma_{i+1}(\ell) \Sigma_{i+1}(m),
\]

and the same argument as in Proposition 3.6 applies. \( \square \)
4. Growth of the groups $W_\omega$

Recall that $W_\omega$ is the permutational wreath product of a group $A$ with $G_\omega$. We estimate the growth of $W_\omega$ in terms of its inverted orbit growth as follows:

**Lemma 4.1.** — Let $A$ have growth $v_A$, and let $G$ have growth $v_G$. Let the inverted orbit growth of $G$ on $(X, \ast)$ be $\Delta$, and let its inverted orbit choice growth be $\Sigma$. Assume that $v_A$ is log-concave. Consider $W = A \wr_\times X G$. Then

$$v_G(R)v_A(R/\Delta(R))^{\Delta(R)} \lesssim v_W(R) \lesssim v_G(R)v_A(R/\Delta(R))^{\Delta(R)}\Sigma(R).$$

**Proof.** — We begin by the lower bound. For $n \in \mathbb{N}$, consider a word $w$ of norm $R$ realizing the maximum $\Delta(R)$; write $O(w) = \{x_1, \ldots, x_k\}$ for $k = \Delta(R)$. Choose then $k$ elements $a_1, \ldots, a_k$ of norm $\leq R/k$ in $A$. Define $f \in \sum X A$ by $f(x_i) = a_i$, all unspecified values being 1. Then $wf \in W$ may be expressed as a word of norm $R + |a_1| + \cdots + |a_k| \leq 2R$ in the standard generators of $W$.

Furthermore, different choices of $a_i$ yield different elements of $W$; and there are $v_A(R/k)^k$ choices for all the elements of $A$. This proves the lower bound.

For the upper bound, consider a word $w$ of norm $R$ in $W$, and let $f \in \sum X A$ denote its value in the base of the wreath product. The support of $f$ has cardinality at most $\Delta(R)$, and may take at most $\Sigma(R)$ values.

Write then $\sup(f) = \{x_1, \ldots, x_k\}$ for some $k \leq \Delta(R)$, and let $a_1, \ldots, a_k \in A$ be the values of $w$ at its support; write $\ell_i = ||a_i||$. Since $\sum \ell_i \leq R$, the norms of the different elements on the support of $f$ define a composition of a number not greater than $R$ into at most $k$ summands; such a composition is determined by $k$ “marked positions” among $R + k$, so there are at most $\left(\begin{array}{c} R+k-1 \\ k \end{array}\right)$ possibilities, which we bound crudely by $R^k/k!$. Furthermore, if $A$ is finite, then no such composition occurs in the count, because the norms of the $a_i$ are bounded. Each of the $a_i$ is then chosen among $v_A(\ell_i)$, elements, and again (by the assumption that $v_A$ is log-concave) there are $\prod v_A(\ell_i) \leq v_A(R/k)^k$ total choices for the elements in $A$. In all cases, therefore, the $\left(\begin{array}{c} R+k-1 \\ k \end{array}\right)$ term is absorbed by $v_A(R/k)^k$: if $A$ is finite, then as we argued there is no binomial term, while if $A$ is infinite then $v_A(R) \gtrsim R$.

We have now decomposed $w$ into data that specify it uniquely, and we multiply the different possibilities for each of the pieces of data. Counting the possibilities for the value of $w$ in $G$, the possibilities for its support
in $X$, and the possibilities for the elements in $A$, we get
\[ v_W(R) \preceq v_G(R)v_A(R/k)^k\Sigma(R), \]
which is maximized by $k = \Delta(R)$.

The previous section then shows:

**Corollary 4.2.** — There are two absolute constants $F, E > 1$ such that the growth function $v$ of $W_\omega = A \wr X G_\omega$ satisfies
\[ E^2k \leq v(\eta_0 \cdots \eta_{k-1} \mu_k) \leq F^2k. \]

**Proof.** — Take together the upper bound on the growth of $G_\omega$ from Proposition 3.6, the bounds on the inverted orbit growth from Proposition 3.9, and the choices for the inverted orbits from Proposition 3.10. The conclusion follows from Lemma 4.1.

We now estimate what the growth of $W_\omega$ for periodic sequences $\omega$. We start by the easy

**Lemma 4.3.** — Let $v, v': \mathbb{N} \to \mathbb{N}$ be increasing functions such that $v(R_t) \leq v'(R_t)$ for an strictly increasing sequence $R_1, R_2, \ldots$ with $R_{t+1}/R_t$ bounded. Then $v \preceq v'$.

**Proof.** — Say $R_{t+1}/R_t \leq K$ for all $t \in \mathbb{N}$. Given $R \in \mathbb{N}$, let $t \in \mathbb{N}$ be such that $R_{t-1} < R \leq R_t$. Then
\[ v(R) \leq v(R_t) \leq v'(R_t) \leq v'(KR), \]
so $v \preceq v'$.

The following result isolates a special case of Theorem A; we include it because it constructs groups with additional properties (recursive presentation, self-similarity).

**Proposition 4.4.** — Let $\omega = \omega_0 \cdots \omega_{k-1}$ be a periodic sequence. Let $\eta \in (2, 3)$ be such that
\[ \eta^k = \text{sp. radius}(M_{\omega_{k-1}} \cdots M_{\omega_0}). \]
Then the group $W_\omega$ has growth
\[ v_\omega(R) \sim \exp(R^{\log 2/\log \eta}). \]

**Proof.** — We choose $V_0 \in \Delta$ to be an eigenvector for $M_{\omega_{k-1}} \cdots M_{\omega_0}$. Then its eigenvalue is $\eta_{k-1} \cdots \eta_0$, and coincides with its spectral radius. Indeed the maps $\overline{M}_x$ are contracting on $\Delta$, so $M_{\omega_{k-1}} \cdots M_{\omega_0}$ has precisely one real eigenvalue. We get $\eta_{k-1} \cdots \eta_0 = \eta^k$. It suffices to estimate the
growth function $w(R)$ of $W_\omega$ at exponentially-spaced values $(\eta_{k-1} \cdots \eta_0)^t$ for $t \in \mathbb{N}$, by Lemma 4.3, and at these places we have, by Corollary 4.2,

$$E^{2^{kt}} \leq v(\eta^{kt}\mu_0) \leq F^{2^{kt}} \quad \text{for all } t \in \mathbb{N},$$

so, for all $R_t = \eta^{kt}\mu_0$, we get

$$E^{(R_t/\mu_0)^{\log 2/\log \eta}} \leq v(R_t) \leq F^{(R_t/\mu_0)^{\log 2/\log \eta}}. \quad \square$$

Note that, because $(V_0, \omega)$ is periodic, the $V_i$ define a discrete sequence in $\Delta$ and in particular do not accumulate on its boundary, so the function $\mu$ is bounded from below on $\{V_i\}$. More care is needed in the general case.

4.1. Dynamics on the simplex

We now show that the spectral radii in Proposition 4.4 are dense in the interval $[2, \eta_+]$. For that purpose, it is useful to translate the problem to a slightly different language.

Let $f$ be the projection of $s^{-1}$ to $\Delta'$. This is a 3-to-1 map, and is expanding for the Hilbert metric on $\Delta$, because the $M_\omega$ are contracting. Periodic orbits under $f$ correspond bijectively to $s$-periodic orbits in $\Omega^+$, by reading them backwards. Indeed, the $\omega$-coordinate can be uniquely recovered by noting in which subsimplex of $\Delta'$ the point lies.

More precisely, if $f^kq = q$, then for $i \in \{0, \ldots, k\}$ let $\omega_i$ be such that $f^{k-i}(q)$ belongs to the image of $M_{\omega_i}$, and extend the sequence $\omega$ periodically. Then the $f$-orbit of $q$ is the reverse of the $s$-orbit of $(q, \omega)$.

Recall that $\eta$ is a continuous function on the simplex; it equals 2 on the boundary, and 3 at the barycentre of $\Delta$. Write $\theta(p) = \log \eta(p)$. For a periodic point $p$, of period $k$, write $\theta^+(p)$ the Cesàro average of $\theta$ on $p$:

$$\theta^+(p) := \frac{1}{k} \left( \theta(p) + \theta(fp) + \cdots + \theta(f^{k-1}p) \right).$$

**Lemma 4.5.** — Let $p$ be an $f$-periodic point of period $k$ in $\Delta'$. Let $\omega_0, \ldots, \omega_{k-1}$ be the corresponding address. Then the spectral radius of $M_{\omega_{k-1}} \cdots M_{\omega_0}$ equals $k\theta^+(p)$.

**Proposition 4.6.** — The averages $\theta^+(p)$ are dense in $[\log 2, \log \eta_+]$.

**Proof.** — Consider $p, p' \in \Sigma$ two periodic points, say of period $k, k'$ respectively.

Because $f$ is expanding, there exist arbitrarily small open sets $U \subset \Delta$ containing $p$, such that $U \subset f^k(U)$ and $f^k$ uniformly expands on $U$; similarly $f^{k'}$ uniformly expands on the neighbourhood $U' \subset \Delta$ of $p'$. Without loss of generality, we assume $U$ and $U'$ are relatively compact.
For any finite sequence $\omega_1 \cdots \omega_n \in \{0, 1, 2\}^n$, consider the fixed point $p_\omega$ of $M_{\omega_n} \cdots M_{\omega_1}$. The triangles $M_{\omega_n} \cdots M_{\omega_1}(\Delta)$ become arbitrarily small, as $n \to \infty$ and all three symbols occur in $\omega_1 \cdots \omega_n$; so periodic points are dense in $\Delta$.

It then follows that, for every non-empty open set $O$, we have $\bigcup_{n \geq 0} f^n(O) = \Delta$; indeed $\bigcup_{n \geq 0} f^n(O)$ is open, and contains all periodic points because $f$ is expanding.

Because $\theta$ is continuous on $\Delta$, for any $\epsilon > 0$ we can make $U$ small enough so that $\frac{1}{k}(\theta(q) + \theta(f(q)) + \cdots + \theta(f^{k-1}(q)))$ is less that $\epsilon$ away from $\theta^+(p)$, for all $q \in U$. Similarly, $U'$ may be chosen small enough that the average of $\theta$ on the first $k'$ points of the orbit of $q'$ is at most $\epsilon$ away from $\theta^+(p')$, for all $q' \in U'$.

Since $U'$ is relatively compact, there exists $\ell \in \mathbb{N}$ such that $U' \subset f^\ell(U)$ and $f^\ell$ uniformly expands on $U$; similarly $U \subset f^\ell(U')$ for some $\ell' \in \mathbb{N}$.

Consider now $n, n' \in \mathbb{N}$. We have locally defined contractions $f^{-k}: U \to U$, $f^{-\ell}: U' \to U$, $f^{-k'}: U' \to U'$ and $f^{-\ell'}: U \to U'$, which we compose:

$$U \xrightarrow{f^{-\ell'}} U' \xrightarrow{f^{-n'k'}} U' \xrightarrow{f^{-\ell}} U \xrightarrow{f^{-nk}} U.$$  

This is a contraction $U \to U$, so by the Banach fixed point theorem there exists a fixed point $q \in U$ for the composite $f^{\ell+nk+\ell'+n'k'}$ that remains close to the orbit of $p$ for $nk$ steps, wanders for $\ell$ steps, remains close to the orbit of $p'$ for $n'k'$ steps, and wanders back to $q$ for $\ell'$ steps.

The average of $\theta$ on $q$ is

$$\theta^+(q) = \frac{1}{nk + \ell + n'k' + \ell'} \left( \theta(q) + \cdots + \theta(f^{nk+\ell+n'k'+\ell'-1}(q)) \right).$$

The orbit of $q$ is, except at $\ell + \ell'$ instants, either close to the orbit of $p$ or close to the orbit of $p'$. Consider any $\rho \in \mathbb{R}_+$. Then, as $n, n' \to \infty$ with ratio $n/n' \to \rho$, we have

$$\lim \inf_{n,n' \to \infty} \theta^+(q) \leq \frac{\rho k(\theta^+(p) + \epsilon) + k'(\theta^+(p') + \epsilon)}{\rho k + k'},$$

and

$$\lim \sup_{n,n' \to \infty} \theta^+(q) \geq \frac{\rho k(\theta^+(p) - \epsilon) + k'(\theta^+(p') - \epsilon)}{\rho k + k'}.$$  

Letting $\epsilon$ tend to $0$ and simultaneously considering all possible $\rho$, we obtain a dense set of values in $[\theta^+(p), \theta^+(p')]$. More precisely, for any $t \in [\theta^+(p), \theta^+(p')]$, let $\rho$ be such that $(\rho k \theta^+(p) + k' \theta^+(p'))/(\rho k + k') = t$; then for any $\epsilon > 0$ there exists $U, U'$ as above; then $\ell, \ell'$ as above; and finally $n, n'$ large enough so that $|\theta^+(q) - t| < 2\epsilon$.  

TOME 64 (2014), FASCICULE 5
Finally, note that we can take for \( p \) the periodic orbit corresponding to the sequence \( \omega = \overline{012} \); while for \( p'\) we consider the periodic point corresponding to the sequence \( \omega' = \overline{0u12} \) for \( u \) sufficiently large; we have \( \theta^+(p') \to \log 2 \) as \( u \to \infty \).

\[ \square \]

### 4.2. Proof of Theorem B

Let \( \omega \) be a periodic sequence, and let \( A \) be a finite group. We already showed in Proposition 2.4 that \( W_\omega \) is self-similar and branched. To show that it is contracting, we endow it with the following metric. It is generated by \( \{1, a, b, c, d\} \times A \); for \( s \in \{a, b, c, d\} \) and \( t \in A \), the norm of \( st \) is \( \|s\| \), while for \( t \neq 1 \) in \( A \) its norm is \( \|a\| \).

We start by a more general result, which holds for arbitrary sequences \( \omega \). Recall from §3 that we set \( G_i = G_{s_i, \omega} \) and selected metrics \( \|\cdot\|_i \) on \( G_i \), giving constants \( \eta_i \). We set \( W_i = A \wr X G_i \), with the metric above.

The reason we can achieve lower bounds on the growth of \( W_i \) may be illustrated as follows; though we will not use it directly. Consider the corresponding permutational wreath products \( W_i = A \wr X G_i \), and note that we also have injective homomorphisms \( \psi_i : W_i \to W_{i+1} \wr S_2 \). The maps \( \psi_i \) have the same Lipschitz property as \( \phi_i \), see Lemma 4.7. Additionally, for all elements of \( W_i \) with sufficiently large support (and there are sufficiently many so as to dominate the asymptotics), we have a reverse inequality \( \|\psi_i(g)\| \geq 2/\eta_i\|g\| - C \).

The following combines Lemma 3.3 and [4, Lemma 4.2]; we only sketch the proof since it follows closely that of its models.

**Lemma 4.7.** — For each \( i \geq 0 \) and each \( g \in W_i \), with \( \psi_i(g) = \langle \langle g_1, g_2 \rangle \rangle \pi \), we have

\[ \|g_1\|_{i+1} + \|g_2\|_{i+1} \leq 2\|a\|_{i+1} + \frac{2}{\eta_i} (\|g\|_i + \|a\|_i). \]

**Proof.** — Consider a minimal representation \( g = s_1t_1 \cdots s_nt_n \) of \( g \in W_i \) with the \( s_j \)'s in \( \{1, a, b, c, d\} \) and the \( t_j \)'s in \( A \). Recall that we have \( \psi_i : W_i \to W_{i+1} \wr S_2 \), defined on generators by \( \psi_i(s) = \phi_i(s) \) for \( s \in \{a, b, c, d\} \), and \( \psi_i(t) = \langle \langle 1, t \rangle \rangle \) for \( t \in A \). Therefore, \( \{b, c, d\} \) commutes with \( A \) in \( W_i \); so (by minimality) we may assume that no two consecutive \( s_j, s_{j+1} \) belong to \( \{b, c, d\} \).

It follows that we have \( g = a^\epsilon x_1t_1ax_2t_2 \cdots ax_m t_m \), with \( \epsilon \in \{0, 1\} \), all \( x_2, \ldots, x_{m-1} \in \{b, c, d\} \), \( x_1, x_m \in \{1, b, c, d\} \), and \( m \leq (n + 1)/2 \). We then proceed as in Lemma 3.3, to construct words representing \( g_1, g_2 \). Each \( t_j \)
contributes a $t_j$ to either $g_1$ or $g_2$; each $x_j$ contributes a letter in $\{1, a, b, c, d\}$ to each of $g_1$ and $g_2$. Therefore, $g_1$ has the form $u_0y_1u_1 \cdots y_mu_m$ for some $u_j \in A$ and $y_i \in \{1, a, b, c, d\}$, while $g_2$ has the similar form $v_0z_1v_1 \cdots z_mv_m$. Furthermore, $\|y_j\|_{i+1} + \|z_j\|_{i+1} \leq 2/\eta_i \|ay_j\|$, by (3.2). Then $\|g_1\|_{i+1} + \|g_2\|_{i+1} \leq \|u_0\|_{i+1} + \|v_0\|_{i+1} + 2/\eta_i (\|g\|_i + \|a\|_i)$, as was to be shown. \hfill \qed

We finally recall a classical estimate of growth as a function of sum-contraction:

**Lemma 4.8** (See e.g. [1], Proposition 4.3). — If $G$ is self-similar and sum-contracting with contraction $\eta$, then $v_G \lesssim \exp(R \log \frac{d}{\log \eta})$.

**Proof of Theorem B.** — Lemma 4.7 gives an upper bound on the growth of $W_\omega$; the same upper bound comes from Proposition 4.4. The density of the growth exponents in $[\alpha, 1]$ follows from Proposition 4.6.

To obtain torsion-free examples, apply Lemma 4.1, recalling that the growth of $\tilde{G}_\omega$ is equivalent to that of $\mathbb{Z} \wr G_\omega$, see §2.3. \hfill \qed

## 5. Proof of Theorem A

We now obtain more growth functions by considering $W_\omega$ and $\tilde{G}_\omega$ for non-periodic sequences $\omega$. We first give an estimate for $\mu_k$; only the first part of Lemma 5.1 will be used.

For a finite sequence $\omega = \omega_0 \cdots \omega_{n-1} \in \{0, 1, 2\}^n$ and $p \in \Delta$, we write by extension

$$M_\omega = M_{\omega_0} \cdots M_{\omega_{n-1}} : \Delta \to \Delta$$

and

$$\eta(p, \omega_0 \cdots \omega_{n-1}) = \eta(p, \omega_0)\eta(M_{\omega_0}p, \omega_1) \cdots \eta(M_{\omega_1} \cdots \omega_{n-2}p, \omega_{n-1}).$$

Fix also once and for all $V_0 \in \Delta'$. When a sequence $\omega$ is under consideration, it defines $V_k \in \Delta'$ and $\eta_k, \mu_k$ by $V_{k+1} = M_{\omega_k}(V_k)$ and $\eta_{k+1} = \eta(V_k, \omega_k)$ and $\mu_k = \mu(V_k)$.

**Lemma 5.1.** — Consider $\omega \in \{0, 1, 2\}^\infty$. For $k \in \mathbb{N}$, let $\ell \in \mathbb{N}$ be maximal such that $\omega_{k-\ell+1} \cdots \omega_k$ contains only two of the symbols 0, 1, 2, say $a, b$. Furthermore write $\omega_{k-\ell+1} \cdots \omega_k = a^{i_1}b^{j_1} \cdots a^{i_m}b^{j_m}$ with $m$ minimal. Then

$$K/m \leq \mu_k \leq L/m$$

for absolute constants $K, L$. 

TOME 64 (2014), FASCICULE 5
Proof. — Without loss of generality, we assume $\omega = \cdots 01^t20^{i_1} \cdots 1^{j_m}$, with $i_1 + \cdots + j_m = \ell$. We have $M_{0^n} = \begin{pmatrix} 1 & 2^n - 1 & 2^n - 1 \\ 0 & 2^n & 0 \\ 0 & 0 & 2^n \end{pmatrix}$.

The image of $M_0$ is the open triangle spanned by $\left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right)$, $\left(\frac{1}{2}, 0, \frac{1}{2}\right)$ and $\left(\frac{1}{2}, \frac{1}{2}, 0\right)$. The image of $M_{01^n}$ is contained in the open triangle spanned by $\left(\frac{1}{4}, \frac{1}{4}, \frac{1}{4}\right)$, $\left(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}\right)$ and $\left(\frac{1}{2}, \frac{1}{2}, 0\right)$. The image of $M_{012}$ is contained in the open triangle spanned by $\left(\frac{1}{5}, \frac{2}{5}, \frac{2}{5}\right)$, $\left(\frac{2}{7}, \frac{2}{7}, \frac{2}{7}\right)$ and $\left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right)$. It follows that $V_{k-\ell}$ belongs to that triangle, so $\mu_{k-\ell} \in \left(\frac{1}{5}, \frac{1}{3}\right)$ is bounded away from 0.

Now, under application of $0, 1$, the third coordinate of $V_{k-\ell+n}$ decreases as $n$ increases, while the first two approach $1/2$. To understand how exactly, we consider $V = (1/2 - \rho \epsilon, 1/2 - (1 - \rho) \epsilon, \epsilon)$ for some $\epsilon \ll 1$ and $\rho \in (\frac{1}{2}, 1)$, and compute

\begin{equation}
M_{0^n}(V) = \begin{pmatrix} \frac{1}{2} - 2^{-n} \rho \epsilon + O(\epsilon^2) \\ (\frac{1}{2} - (1 - 2^{-n} \rho) & \epsilon + O(\epsilon^3) \\ \epsilon - 2\rho (1 - 2^{-n}) \epsilon^2 + O(\epsilon^3) \end{pmatrix}.
\end{equation}

A similar approximation holds for $M_{1^n}(V)$, with the first two rows switched.

Write $W = M_{0^n}(V)$. It follows that $\mu(W) \approx \epsilon - Ae^2$ is bounded away from 0 as $n \to \infty$, with $A \in (\frac{1}{2}, 1)$. On the other hand, if $n \geq 1$, then $W$ is of the form $(1/2 - (1 - \rho') \epsilon', 1/2 - \rho' \epsilon'$, $\epsilon')$ for $\epsilon' \approx \epsilon - Ae^2$ and some $\rho' \in (\frac{1}{2}, 1)$. Set $X = M_{1^n}(W)$; then $\mu(X) \approx \epsilon' - 2\rho'(1 - 2^{-n})\epsilon'(\epsilon')^2 = \epsilon' - B(\epsilon')^2$ for some $B \in (\frac{1}{2}, 1)$.

If we now translate to coordinates $\epsilon = 1/N$, we get $\mu(V) = 1/N, \mu(W) \approx 1/(N + A)$ and $\mu(X) \approx 1/(N + A + B)$ with $A, B \in (\frac{1}{2}, 1)$. We repeat this $m$ times, giving $\mu(V_k) \approx 1/(N + A_1 + B_1 + \cdots + A_m + B_m)$ with $A_i, B_i \in (\frac{1}{2}, 1)$ if $\mu(V_{k-\ell}) \approx 1/N$. This translates to $K = 1, L = 2$ in the statement of the lemma. In fact, the constants are a bit worse because of the approximations we made in (5.1), that are accurate only for small $\mu$. \hfill \Box

Corollary 5.2. — If the sequence $\omega$ has the form

\begin{equation}
\omega = (012)^{i_1}2^{j_1}(012)^{i_2}2^{j_2}(012)^{i_3}2^{j_3} \cdots,
\end{equation}

with $i_1, j_1, i_2, j_2, \ldots \geq 1$, then the $\mu_k$ are all bounded away from 0.

Proof. — In fact, the image of $M_{012}$ is the open triangle spanned by $\left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right)$, $\left(\frac{2}{7}, \frac{2}{7}, \frac{2}{7}\right)$ and $\left(\frac{4}{17}, \frac{6}{17}, \frac{7}{17}\right)$, so after each $012$ the $\mu_k$ belongs to $\left(\frac{4}{17}, \frac{1}{2}\right)$.

The image of that triangle under $M_{2^n}$ is contained in the convex quadrilateral spanned by $\left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right)$, $\left(\frac{4}{17}, \frac{6}{17}, \frac{7}{17}\right)$, $\left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right)$ and $\left(\frac{1}{3}, \frac{2}{10}, \frac{1}{3}\right)$, so $\mu_k \in \left(\frac{1}{5}, \frac{1}{3}\right)$ for all $k$. \hfill \Box

ANNALES DE L’INSTITUT FOURIER
We also show that $\eta$ converges very fast to its limiting values under periodic orbits:

**Lemma 5.3.** — There exist constants $A' \leq 1$, $B' \geq 1$ such that

1. For all $V \in \Delta'$ and all $n \in \mathbb{N}$,
   $$\eta(V, (012)^n) \geq \eta_+^3 A';$$
2. For all $V \in \Delta'$ and all $n \in \mathbb{N}$,
   $$\eta(V, 2^n) \leq 2^n B'.$$

**Proof.** — Let $V_+ \in \Delta$ denote the fixed point of $\overline{\mathcal{M}}_{012}$. Note first that $\eta(-, 012)$ is differentiable at $V_+$, and that $\overline{\mathcal{M}}_{012}$ is uniformly contracting about $V_+$. Let $\mathcal{U}$ be a neighbourhood of $V_+$ such that $\overline{\mathcal{M}}_{012}$ is $\rho$-Lipschitz in $\mathcal{U}$, and let $D$ be an upper bound for the derivative of $\log \eta(-, 012)$ on $\mathcal{U}$. We may assume, without loss of generality, that $\mathcal{U}$ contains the image of $\overline{\mathcal{M}}_{012}$. Recall that $\eta_+^3 = \eta(V_+, 012)$.

For all $k \in \mathbb{N}$, write $V_k = \overline{\mathcal{M}}_{012}^k(V)$. For $k \geq 1$ we have $d(V_k, V_+) \leq \rho^{k-1}$, so $|\log \eta(V_k, 012) - 3 \log \eta_+| < D \rho^{k-1}$, while for $k = 0$ we write $|\log \eta(V, 012) - 3 \log \eta_+| < 3 \log 3$. Therefore,

$$|\log \eta(V, (012)^n) - 3n \log \eta_+| \leq 3 \log 3 + \sum_{k=1}^{n-1} |\log \eta(V_k, 012) - 3 \log \eta_+|$$

is bounded over all $n$ and $V$. The estimate (1) follows, with $A' = 3^3 \exp(D/(1 - \rho))$.

For the second part, consider $V_k = \overline{\mathcal{M}}_{2^k}(V)$, and note that $V_k$ converges to a point $V_{\infty}$ on the side $\{\delta = \frac{1}{2}\}$ of $\Delta$. By the approximations (5.1), we get $d(V_k, V_{\infty}) \approx 2^{-k}$, so definitely $d(V_k, V_{\infty}) < \rho^{k-1}$ for some $\rho < 1$. As above, $\eta(-, 2)$ is differentiable in a neighbourhood $\mathcal{U}$ of $\{\delta = \frac{1}{2}\}$, and the derivative of $\log(2)$ is bounded on $\mathcal{U}$, say by $D$. We may again assume, without loss of generality, that $\mathcal{U}$ contains the image of $\overline{\mathcal{M}}_{2}$. Recall that $\eta(V, 2) = 2$ for all $V$ on $\{\delta = \frac{1}{2}\}$.

As before, for $k \geq 1$ we have $|\log \eta(V_k, 2) - \log 2| < D \rho^{k-1}$, while for $k = 0$ we write $|\log \eta(V, 2) - \log 2| < 3 \log 3$. Therefore,

$$|\log \eta(V, 2^n) - n \log 2| \leq 3 \log 3 + \sum_{k=1}^{n-1} |\log \eta(V_k, 2) - \log \eta_+|$$

is bounded over all $n$ and $V$. The estimate (1) follows, with $B' = 3 \exp(D/(1 - \rho))$. \qed
We now reformulate the statement of Theorem A as follows. For the main statement, set \( g(R) = \log f(R) \); to construct a torsion-free group as in Remark 1.1, define \( g \) implicitly by \( (R/g(R))^{g(R)} = f(R) \). In both cases, we obtain
\[
(5.3) \quad g(2R) \leq 2g(R) \leq g(\eta+R)
\]
for all \( R \) large enough. For simplicity (since growth is only an asymptotic property) we assume that (5.3) holds for all \( R \). Without loss of generality, we also assume that \( g \) is increasing and satisfies \( g(1) = 1 \).

Recall that an initial metric \( V_0 \in \Delta' \) has been chosen. We will construct a sequence \( \omega \) such that, for constants \( A, B \), we have
\[
(5.4) \quad A \leq \frac{g(\eta(V_0, \omega_0 \cdots \omega_{k-1}))}{2^k} \leq B \quad \text{for all } k;
\]
in fact, it will suffice to obtain this inequality for a set of values \( k_0, k_1, \ldots \) of \( k \) such that \( \sup_i (k_{i+1} - k_i) < \infty \). Indeed, the orbit \( V_i \) of \( V_0 \) in \( \Delta' \) will remain bounded, so we will have \( \mu(V_i) \in [C, 1] \) for some \( C > 0 \). Consider for simplicity the first part of the theorem, for which \( g(R) = \log f(R) \). Then, by Corollary 4.2,
\[
E^{2^k} \leq v(\eta(V_0, \omega_0 \cdots \omega_{k-1}) \mu_k) \leq v(Bg^{-1}(2^k)),
\]
\[
v(ACg^{-1}(2^k)) \leq v(\eta(V_0, \omega_0 \cdots \omega_{k-1}) \mu_k) \leq F^{2^k}
\]
and therefore \( v(R) \sim \exp(g(R)) = f(R) \). Similar considerations hold for the torsion-free case of Remark 1.1, using Lemma 4.1.

**Proof of (5.4).** — We will construct a sequence \( \omega \) of the form (5.2),
\[
\omega = (012)^{i_1}2^{j_1}(012)^{i_2}2^{j_2}(012)^{i_3}2^{j_3} \cdots ,
\]
with \( i_1, j_1, i_2, j_2, \ldots \geq 1 \). The \( \mu_k \) are bounded away from 0 by Corollary 5.2.

We start by the empty sequence. Then, assuming \( \omega' = \omega_0 \cdots \omega_{k-1} \) has been constructed, we repeat the following:

- while \( g(\eta(V_0, \omega')) < 2^k \), we append \( 012 \) to \( \omega' \);
- while \( g(\eta(V_0, \omega')) > 2^k \), we append \( 2 \) to \( \omega' \).

For our induction hypothesis, we assume that the stronger condition
\[
\frac{1}{2} 2^k \leq g(\eta(V_0, \omega')) \leq 2^k
\]
holds for each \( k \) of the form \( i_1 + j_1 + \cdots + i_m + j_m \), and that
\[
2^k \leq g(\eta(V_0, \omega')) \leq 3^3 2^k
\]
holds for each \( k \) of the form \( i_1 + j_1 + \cdots + i_m \); these conditions apply whenever \( \omega \) is a product of ‘syllables’ \( (012)^{i_1} \) and \( 2^{j_i} \).
Consider first the case $\frac{1}{2}2^k \leq g(\eta(V_0, \omega')) \leq 2^k$; and let $n$ be minimal such that $g(\eta(V_0, \omega'(1012)^n)) > 2^{k+3n}$. Then, for all $i \in \{1, \ldots, n\}$, Lemma 5.3(1) gives $\eta(V_0, \omega'(1012)^i) > \eta(V_0, \omega')^{2i}A'$. Let $u \in \mathbb{N}$ be minimal such that $A' \geq n^u$; this, combined with $g(\eta_i R) \geq 2g(R)$, gives

$$g(\eta(V_0, \omega'(1012)^i)) \geq g(\eta(V_0, \omega')^{2i}A') \geq 2^{-1-u}2^{k+3i}.$$ 

By minimality of $n$, we have $g(\eta(V_0, \omega'(1012)^{n-1})) \leq 2^{k+3(n-1)}$; since $g$ is sublinear and $n \leq 3$, we get

$$g(\eta(V_0, \omega'(1012)^n)) \leq 3^{3}2^{k+3n}.$$

Consider then the case $2^k \leq g(\eta(V_0, \omega')) \leq 3^32^k$, which is similar, and let $n$ be minimal such that $g(\eta(V_0, \omega'2^n)) < 2^{k+n}$. Then, for all $i \in \{1, \ldots, n\}$, Lemma 5.3(2) gives $\eta(V_0, \omega'2^i) \leq \eta(V_0, \omega')2^i B'$; this, combined with $g(2R) \leq 2g(R)$, gives

$$g(\eta(V_0, \omega'2^i)) \leq 3^{3}2^{k+i} B'.$$

By minimality of $n$, we have $g(\eta(V_0, \omega'2^{n-1})) \geq 2^{k+n-1}$; since $g$ is increasing, we get

$$g(\eta(V_0, \omega'2^n)) \geq \frac{1}{2}2^{k+n}.$$

We have proved the claim (5.4), with $A = 2^{-1-u}$ and $B = 3^3B'$. \hfill \Box

Remark 5.4. — The construction of $\omega$ from $f$ is algorithmic, in the following sense. If $V_0$ is chosen with rational coefficients, then all $V_k$ have rational coefficients, and therefore are be computable. Furthermore, $\eta(V_0, \omega_0 \cdots \omega_k)$ is also computable. Therefore, if $f$ is recursive, then so is $\omega$.

It then follows that $G_\omega, \tilde{G}_\omega$ and $W_\omega = \Phi X G_\omega$ are recursively presented (for recursively presented $A$), see §2.2 and §2.4.

5.1. Illustrations

Given a sufficiently regular growth function $f$, Theorem A constructs a sequence $\omega$ such that the growth of $W_\omega$ is asymptotically $f$. We may proceed the other way round, and consider “regular” sequences $\omega$, using then Corollary 4.2, Corollary 5.2 and Lemma 5.3 to estimate the growth of $W_\omega$. Here are four examples:

- Consider the sequence $\omega = (1012)2^1(012)2^2(012)2^3(012)2^4 \cdots$.

  Among the first $k$ entries, approximately $\sqrt{k}$ instances of $012$ will have been seen; therefore $\eta(V_0, \omega_0 \cdots \omega_{k-1}) \approx 2^{k+O(1)\sqrt{k}}$. This gives a growth function of the order of

  $$\exp(R/\exp(O(1)\sqrt{\log R})).$$

  exp(R/ exp(O(1) √ log R)).
• Consider the sequence $\omega = (012)2^1 (012)2^2 (012)2^4 (012)2^8 \cdots$. Among the first $k$ entries, approximately $\log k$ instances of $012$ will have been seen; therefore $\eta(V_0, \omega_0 \cdots \omega_{k-1}) \approx 2^k + O(1) \log k$. This gives a growth function of the order of $\exp(R/(\log R))^{O(1)}$.

• Consider the sequence $\omega = (012)2^2 (012)2^2 (012)2^4 (012)2^2 \cdots$. Among the first $k$ entries, approximately $\log \log k$ instances of $012$ will have been seen; therefore $\eta(V_0, \omega_0 \cdots \omega_{k-1}) \approx 2^k + O(1) \log \log k$. This gives a growth function of the order of $\exp(R/(\log \log R))^{O(1)}$.

• Consider the Ackermann function

$$A(m, n) = \begin{cases} 
  n + 1 & \text{if } m = 0, \\
  A(m - 1, 1) & \text{if } m > 0 \text{ and } n = 0, \\
  A(m - 1, A(m, n - 1)) & \text{if } m > 0 \text{ and } n > 0,
\end{cases}$$

and consider $\omega = (012)2^{A(0,0)} (012)2^{A(1,1)} (012)2^{A(2,2)} \cdots$. Then $W_\omega$ is a group of subexponential growth, whose growth is larger than any primitive recursive function of subexponential growth.

Thanks. — We express our gratitude to Bill Thurston for explanations and discussions on the topic of dynamics on the simplex and on the density of $\eta$-averages as in Theorem B, which he generously contributed during a conference in Roskilde in September 2010.

We are also grateful to Slava Grigorchuk and Pierre de la Harpe for their comments on a previous version of this article.
