GEOMETRIC STRUCTURES AND THE LAPLACE SPECTRUM, PART I

by Samuel LIN, Benjamin SCHMIDT & Craig SUTTON (*)

Abstract. — Inspired by the central role geometric structures play in our understanding of the taxonomy of three-manifolds, we initiate the exploration of the extent to which compact locally homogeneous three-manifolds are characterized up to universal Riemannian cover by their spectra. Using the first four heat invariants, we conclude that within the universe of compact locally homogeneous Riemannian manifolds, closed three-manifolds equipped with geometric structures modeled on six of the eight Thurston geometries are determined up to universal Riemannian cover by their spectra, a result that includes all compact locally symmetric three-manifolds and is optimal due to the existence of isospectral hyperbolic three-manifolds, for example. Furthermore, we show that any space modeled on the symmetric space $S^2 \times E$ or Nil equipped with an arbitrary left-invariant metric is uniquely determined by its spectrum among all locally homogeneous spaces. These results follow from more general observations, regarding the eight “metrically maximal” three-dimensional geometries, that strongly suggest local geometry is “audible” among compact locally homogeneous three-manifolds.

Keywords: Laplace spectrum, heat invariants, geometric structures, three-manifolds.

1. Introduction

Spectral geometry is the study of the relationship between the spectrum of a Riemannian manifold – i.e., the sequence of eigenvalues (counting multiplicities) of the associated Laplace–Beltrami operator – and its underlying geometry. Two Riemannian manifolds are said to be isospectral if their spectra agree and, building off of Kac’s metaphor [20], a geometric property will be called audible, if it is encoded in the spectrum. Numerous examples of isospectral, yet non-isometric spaces demonstrate that, in general, the spectrum does not completely determine the geometry of the underlying Riemannian manifold. Nevertheless, it is expected that certain natural classes of Riemannian manifolds are characterized by their spectra.

For example, it is widely believed that a round $n$-sphere is determined up to isometry by its spectrum. In 1973, Tanno verified this for round spheres of dimension at most six [42, Theorem B]. Seven years later, he also proved that a round metric on an arbitrary $n$-sphere is locally audible [43]; that is, within the space of metrics on the $n$-sphere, each metric of constant positive curvature admits a neighborhood in which it is determined up to isometry by its spectrum. And, recently, Bettiol, Lauret and Piccione have shown that among homogeneous metrics on an odd-dimensional sphere the round metric is uniquely determined by its spectrum (see [6, Theorem C & Section 4]), eliminating a natural source of counterexamples. More generally, one expects the spectrum to encode whether a closed Riemannian manifold has constant sectional curvature $K$; however, this is only known to be true in dimension five and lower (see [4] and [42, Theorem A]).

Given the important role geometric structures (i.e., complete locally homogeneous Riemannian metrics) play in our understanding of surfaces (via the uniformization theorem) and three-manifolds (via the geometrization conjecture) this article explores the extent to which low-dimensional geometric structures are audible. Combining Theorem 1.1 of this article with work of Berger on constant curvature manifolds [4, Theorem 7.1], we obtain the following strong evidence that (1) a compact locally homogeneous three-manifold is determined up to universal Riemannian cover by its spectrum and (2) certain locally homogeneous three-manifolds are uniquely determined by their spectra.

**Main Results. —** There are eight (metrically maximal) geometries, labeled (MM1)–(MM8) on p. 9, upon which all compact locally homogeneous three-manifolds are modeled (see Section 1.1 for details). Among compact locally homogeneous three-manifolds, the following statements are true.
(1) A compact locally homogeneous three-manifold modeled on one of (MM1)–(MM6) is determined up to model geometry by its spectrum (see Theorem 1.1).

(2) A compact three-manifold with universal Riemannian cover isometric to
   (a) a symmetric space,
   (b) $\widetilde{E}(2)$ equipped with a left-invariant metric,
   (c) Nil equipped with a left-invariant metric, or
   (d) $S^3$ equipped with a left-invariant metric sufficiently close to a round metric
is determined up to universal Riemannian cover by its spectrum (see Corollary 1.2).

(3) A compact locally symmetric three-manifold modeled on the geometry $(S^2 \times \mathbb{R}, \text{Isom}(S^2 \times \mathbb{E})^o)$ (respectively, $(\text{Nil}, \text{Nil})$) is determined up to isometry by its spectrum (see Corollaries 1.3 and 1.4).

(4) Two isospectral compact locally homogeneous spaces modeled on the geometry $(\text{Sol}, \text{Sol})$ have isometric universal Riemannian covers (see Proposition 3.22).

We note the existence of non-trivial isospectral pairs covered by $\mathbb{H}^3$, $\mathbb{H}^2 \times \mathbb{E}$ and $\mathbb{E}^3$, respectively [8, 10, 28, 39, 45], demonstrate that, in general, one cannot hope to do better than determining locally homogeneous three-manifolds up to universal Riemannian cover.

The remainder of the introduction is devoted to providing additional background and context, along with a complete statement of the problem under consideration (see Problem A) and precise formulations of the preceding results. Figure 1.2 provides a convenient summary of the state of affairs.

1.1. Geometric structures

Given a smooth manifold $M$, we will let $\mathscr{R}(M)$ denote the space of smooth Riemannian metrics supported by $M$. For any $g \in \mathscr{R}(M)$, $\text{Isom}(M, g)$ will denote the the corresponding group of isometries and $\text{Isom}(M, g)^o$ will denote the connected component of the identity in $\text{Isom}(M, g)$.

By an $n$-dimensional geometry we shall mean a triple $(X, G, \alpha)$ consisting of a smooth simply-connected $n$-dimensional manifold $X$, a connected Lie group $G$, and a smooth transitive effective $G$-action $\alpha : G \times X \to X$
such that, for each \( p \in X \), the stabilizer subgroup \( G_p \) is compact and there is a subgroup \( \Gamma \leq G \) (acting freely and properly discontinuously on \( X \)) so that the manifold \( M = \Gamma \backslash X \) is compact. The condition that the \( G \)-action have compact point stabilizers implies \( \mathcal{R}_G(X) \), the collection of \( G \)-invariant Riemannian metrics on \( X \), is non-empty. Two geometries \((X_1, G_1, \alpha_1)\) and \((X_2, G_2, \alpha_2)\) are said to be equivalent if there is a diffeomorphism \( f : X_1 \to X_2 \) and a Lie group isomorphism \( \Psi : G_1 \to G_2 \) that intertwine the two group actions: 
\[
 f(\alpha_1(g, x)) = \alpha_2(\Psi(g), f(x)) \quad \text{for any } x \in X_1 \text{ and } g \in G_1.
\]
In the event the geometries \((X, H, \beta)\) and \((X, G, \alpha)\) are such that \( H \) is a subgroup of \( G \) and \( \beta \) is the restriction of \( \alpha \), we will say that \((X, H, \beta)\) is a sub-geometry of \((X, G, \alpha)\) and write \((X, H, \beta) \leq (X, G, \alpha)\).

To simplify notation, when the \( G \)-action on \( X \) is understood, we will denote the geometry \((X, G, \alpha)\) by \((X, G)\).

A geometry \((X, G)\) is said to be symmetry maximal\(^{(1)}\) if (up to equivalence) it is not a proper sub-geometry of another geometry. In this case, among the homogeneous Riemannian metrics on \( X \) that admit compact quotients, there is no metric \( h \) with \( \text{Isom}(X, h)^o \) strictly larger than \( G \) and, as a consequence, \( \mathcal{R}_G(X) \) is minimal among \( \mathcal{R}_H(X) \) as \((X, H)\) ranges over geometries on \( X \). It can be shown that every geometry is contained in a symmetry maximal geometry (cf. [11, Proposition 1.1.2]); however, as was recently observed by Geng [12, p. 7], the symmetry maximal geometry need not be unique.

We will say that a geometry \((X, G)\) is metrically maximal, if whenever \((X, H) \leq (X, G) \leq (X, L)\), we have \( \mathcal{R}_L(X) \subseteq \mathcal{R}_G(X) = \mathcal{R}_H(X) \). In this case, among the homogeneous Riemannian metrics on \( X \) that admit compact quotients, \( \mathcal{R}_G(X) \) is a maximal collection of metrics and \( G \) is minimal among \( \text{Isom}(X, h)^o \) as \( h \) ranges over homogeneous metrics on \( X \) admitting compact quotients.\(^{(2)}\) Therefore, up to isometry, the collection of homogeneous metrics on \( X \) covering a compact quotient (abbreviated c.q.) is precisely
\[
 \mathcal{R}_{\text{hom}}^c(X) \equiv \bigcup_{[X, G]} \mathcal{R}_G(X),
\]
where the union is taken over all equivalence classes of metrically maximal geometries on \( X \). Following Scott [36, p. 403], a complete locally homogeneous metric on a manifold \( M \) is called a geometric structure and it is said

\(^{(1)}\) This trait is usually referred to as “maximal”; however, we have chosen the term “symmetry maximal” as it is a bit more descriptive and helps to distinguish it from our new concept of “metrically maximal” which is defined later in the introduction.

\(^{(2)}\) We note that \((X, G)\) being metrically maximal is not the same as being minimal among all geometries on \( X \).

\(\text{ANNALES DE L’INSTITUT FOURIER}\)
to be modeled on the geometry \((X, G)\) if its universal Riemannian cover is isometric to \(X\) equipped with a metric in \(\mathcal{R}_G(X)\). A geometric structure on \(M\) is said to be symmetry maximal if it is modeled on a symmetry maximal geometry.

**The Geometries of Constant Sectional Curvature.** — Let \(\mathbb{E}^n\) be \(n\)-dimensional Euclidean space, \(\mathbb{S}^n\) be the \(n\)-dimensional sphere equipped with the round metric of constant curvature \(+1\) and \(\mathbb{H}^n\) the \(n\)-dimensional upper half-plane equipped with the hyperbolic metric of constant sectional curvature \(-1\). Then, we have the following symmetry maximal simply-connected \(n\)-dimensional geometries:

- \((X = \mathbb{R}^n, G = \text{Isom}(\mathbb{E}^n)^o)\), where (up to isometry) \(\mathcal{R}_G(X)\) consists of the unique flat metric on \(\mathbb{R}^n\);
- \((X = \mathbb{S}^n, G = \text{Isom}(\mathbb{S}^n)^o)\), where (up to isometry) \(\mathcal{R}_G(X)\) consists of the metrics of constant positive sectional curvature on \(\mathbb{S}^n\);
- \((X = \mathbb{H}^n, G = \text{Isom}(\mathbb{H}^n)^o)\), where (up to isometry) \(\mathcal{R}_G(X)\) consists of the metrics of constant negative sectional curvature on \(\mathbb{H}^n\).

That these geometries are symmetry maximal follows from the fact that the dimension of the isometry group of a complete \(n\)-dimensional Riemannian manifold is bounded above by \(\frac{n(n+1)}{2}\) with equality if and only if the space has constant sectional curvature and is either simply-connected or diffeomorphic to real projective space [31, Proposition 6.5].

**Symmetry Maximal vs. Metrically Maximal.** — The geometry \((\mathbb{S}^n, \text{Isom}(\mathbb{S}^n)^o = \text{SO}(n+1))\) is a symmetry maximal geometry on the \(n\)-sphere and, by the classification of connected Lie groups acting transitively on spheres [7, 24], it is the unique symmetry maximal geometry on the sphere. Following Ziller’s classification of the homogeneous metrics on the \(n\)-sphere [46], one deduces that the metrically maximal geometries on spheres are \((\mathbb{S}^{2n}, \text{SO}(2n+1)), (\mathbb{S}^{4n+1}, \text{SU}(2n+1)), (\mathbb{S}^{4n+3}, \text{Sp}(n+1))\) and \((\mathbb{S}^{15}, \text{Spin}(9))\), where \(n\) is a positive integer. Therefore, up to isometry, the space of homogeneous metrics on the \(n\)-sphere is given by

\[
R_{\text{hom}}(\mathbb{S}^n) = \begin{cases} 
R_{\text{SO}(n+1)}(\mathbb{S}^n), & n \equiv 0 \pmod{2}, \\
R_{\text{SU}(\frac{n+1}{2})}(\mathbb{S}^n), & n \equiv 1 \pmod{4}, \\
R_{\text{Sp}(\frac{n+1}{4})}(\mathbb{S}^n), & n \equiv 3 \pmod{4}, n \neq 15, \\
R_{\text{Sp}(4)}(\mathbb{S}^{15}) \cup R_{\text{Spin}(9)}(\mathbb{S}^{15}), & n = 15. 
\end{cases}
\]
and is synonymous with $R_{\text{hom}}^{\text{eq}}(S^n)$, since $S^n$ is compact. Hence, the only homogeneous metrics on even-dimensional spheres are the metrics of constant positive sectional curvature, while odd-dimensional spheres admit multi-parameter families of homogeneous metrics.

Given a geometry $(X, G)$, $X$ equipped with a choice of metric $h \in R_G(X)$ is a simply-connected homogeneous space, and any quotient of $X$ by a subgroup $\Gamma \leq \text{Isom}(X, h)$ of isometries that acts freely and properly discontinuously admits a locally homogeneous metric. Conversely, a result of Singer states that the universal Riemannian cover of a locally homogeneous manifold is itself a homogeneous space [38]. Therefore, to classify the compact $n$-manifolds admitting geometric structures, one should begin by classifying the symmetry maximal geometries. And, to understand all the possible locally homogeneous metrics supported by such spaces, one must classify the metrically maximal $n$-dimensional geometries.

In dimension two, the metrically maximal geometries are precisely the two-dimensional geometries of constant sectional curvature described above, these geometries are also symmetry maximal. Additionally, the uniformization theorem states that any closed surface $\Sigma$ admits geometric structures and the locally homogeneous metrics supported by $\Sigma$ are all modeled on the same symmetry maximal two-dimensional geometry. Turning to the Laplace spectrum, we recall that Berger has shown that a surface of constant sectional curvature is determined up to local isometry by its spectrum. In brief, compact locally homogeneous surfaces – which are important to our understanding of the topology of surfaces (via the uniformization theorem) – are determined up to local isometry by their spectra, and the numerous examples of isospectral Riemann surfaces show this result is optimal. This discussion raises the following questions.

1. Is local homogeneity an audible property?
2. Let $(M_1, g_1)$ and $(M_2, g_2)$ be two isospectral locally homogeneous $n$-manifolds.
   - Does it follow that $(M_1, g_1)$ and $(M_2, g_2)$ are modeled on a common geometry?
   - Does it follow that $(M_1, g_1)$ and $(M_2, g_2)$ are locally isometric?

   What if one restricts their attention to symmetry maximal geometries?

In general, the answer to these questions is no. Indeed, Szabo has demonstrated that local homogeneity is inaudible in dimension 10 and higher [41, Section 3]. Restricting our attention to locally homogeneous spaces, the examples of Gordon [13, 14] demonstrate that in dimension 8 and higher
isospectral locally homogeneous spaces need not be locally isometric (cf. [17, 26, 34, 40]). Furthermore, making use of the third author’s generalization of Sunada’s method [40], An, Yu and Yu [1] demonstrate that isospectral locally homogeneous spaces of dimension at least 26 need not share the same model geometry (cf. [40]). Indeed, they produce examples of isospectral simply-connected homogeneous spaces of dimension at least 26 that are not homeomorphic. We do not know whether any of the examples discussed in this paragraph involve spaces modeled on symmetry maximal geometries.

The celebrated positive resolution of the geometrization conjecture confirms that an orientable prime closed three-manifold admits a canonical decomposition into pieces that each support geometric structures modeled on precisely one of the eight symmetry maximal three-dimensional geometries (see below). Inspired by the special relationship between three-dimensional geometric structures and the topology of three-manifolds, we pose the following problem.

**Problem A.** — *Determine the degree to which the geometry of a three-dimensional geometric structure is encoded in its spectrum. Specifically, let \((M_1, g_1)\) be a compact locally homogeneous three-manifold modeled on the geometry \((X, G)\). Now, suppose \((M_2, g_2)\) is a compact Riemannian three-manifold that shares the same spectrum as \((M_1, g_1)\). Can we conclude that*

- (1) \(\ldots (M_2, g_2)\) is a locally homogeneous Riemannian manifold?
- (2) \(\ldots (M_2, g_2)\) is modeled on \((X, G)\)?
- (3) \(\ldots (M_1, g_1)\) and \((M_2, g_2)\) have isometric universal Riemannian coverings?
- (4) \(\ldots (M_1, g_1)\) and \((M_2, g_2)\) are isometric?

*To what extent do the answers to these questions depend on the specific choice of geometry \((X, G)\) or whether the geometry is symmetry maximal?*

The three-dimensional symmetry maximal geometries have been classified by Thurston and have come to be known collectively as the *Thurston Geometries*. They consist of the geometries associated with each of the three-dimensional symmetric spaces and the symmetry maximal geometries on the unimodular Lie groups Nil, \(\widetilde{SL_2(\mathbb{R})}\) and Sol, where Nil is the group of three-by-three unit upper triangular matrices, \(\widetilde{SL_2(\mathbb{R})}\) is the universal covering group of \(SL_2(\mathbb{R})\), and Sol = \(\mathbb{R}^2 \rtimes \mathbb{R}\) with \(\mathbb{R}\) acting on \(\mathbb{R}^2\) via \(t \cdot (x, y) = (e^t x, e^{-t} y)\).
THE THURSTON GEOMETRIES (see [36, 44]). — A symmetry maximal three-dimensional geometry \((X, G)\) is equivalent to one of the following eight geometries:

(T1) \((\mathbb{R}^3, \text{Isom}(\mathbb{E}^3)^\circ)\),
(T2) \((S^3, \text{Isom}(S^3)^\circ)\),
(T3) \((\mathbb{H}^3, \text{Isom}(\mathbb{H}^3)^\circ)\),
(T4) \((S^2 \times \mathbb{R}, \text{Isom}(S^2 \times \mathbb{E})^\circ)\),
(T5) \((\mathbb{H}^2 \times \mathbb{R}, \text{Isom}(\mathbb{H}^2 \times \mathbb{E})^\circ)\),
(T6) \((\text{Nil}, \text{Isom}(\text{Nil}, g_{\text{max}})^\circ)\), where \(\text{Isom}(\text{Nil}, g_{\text{max}})^\circ\) is four-dimensional, has index two in the full isometry group and is generated by \(\text{Nil}\) acting on itself by left translations and an \(S^1\)-action,
(T7) \((\text{SL}_2(\mathbb{R}), \text{Isom}(\text{SL}_2(\mathbb{R}), g_{\text{max}})^\circ)\), where \(\text{Isom}(\text{SL}_2(\mathbb{R}), g_{\text{max}})^\circ\) is four-dimensional, has index two in the full isometry group and is generated by \(\text{SL}_2(\mathbb{R})\) acting on itself by left translations and an action by \(\mathbb{R}\);
(T8) \((\text{Sol}, \text{Isom}(\text{Sol}, g_{\text{max}})^\circ)\), where \(\text{Isom}(\text{Sol}, g_{\text{max}})^\circ\) is \(\text{Sol}\) and has index eight in the full isometry group.

For the geometries (T6), (T7) and (T8), the metric \(g_{\text{max}}\) is a special metric drawn from the collection of left-invariant metrics on \(G\) (see [36, Section 4]). Additionally, for any compact three-manifold \(M\) admitting geometric structures, the locally homogeneous metrics supported by \(M\) are all modeled on a sub-geometry of a unique symmetry maximal three-dimensional geometry.

Figure 1.1. A cubical tiling of \(\mathbb{H}^3\). (Image courtesy of Steve Trettel.)
It follows from the work of Sekigawa [37, Theorem B] that any proper sub-geometry of a Thurston geometry must be of the form \((G, \text{Isom}(G, g)\circ)\), where \(g\) is a left-invariant metric on \(G\). The work of Raymond and Vasquez shows that the three-dimensional Lie groups giving rise to geometries of this type are precisely \(\mathbb{R}^3\), \(S^3\), Nil, Sol, \(\text{SL}_2(\mathbb{R})\) and \(E(2)\), the universal cover of the isometry group of the Euclidean plane [27]. The geometries arising from the first five of these groups are each a sub-geometry of an obvious (and unique) Thurston geometry, and the geometry \((\mathbb{R}^3, \mathbb{R}^3)\) clearly gives rise to the Euclidean metric on \(\mathbb{R}^3\).

As for geometries of the form \((E(2), \text{Isom}(E(2), g)\circ)\), where \(g\) is a left-invariant metric, first, we note that \(E(2) = \mathbb{R}^2 \rtimes \mathbb{R}\), where \(R : \mathbb{R} \to \text{Aut}(\mathbb{R}^2)\) is the homomorphism that sends \(\theta\) to counterclockwise rotation through \(2\pi\theta\). Then, letting \(\Psi : E(2) = \mathbb{R}^2 \rtimes \mathbb{R} \to \text{Isom}(E^3) = \mathbb{R}^3 \rtimes O(3)\) be the Lie group embedding defined by \(\Psi(v; \theta) = ((v; \theta), R(\theta) \oplus 1)\), one can check that \(\Psi(E(2))\) acts transitively on \(\mathbb{R}^3\) and the geometry \((E(2), E(2))\) is equivalent to \((\mathbb{R}^3, \Psi(E(2)))\). Therefore, \((E(2), E(2))\) is a sub-geometry of \((\mathbb{R}^3, \text{Isom}(E^3)\circ)\) that gives rise to flat metrics and metrics of negative Ricci curvature (see [22, Theorem 1.5 & Corollary 4.8]). In total, there are ten closed three-manifolds — sometimes referred to as “platycosms” [10] — that admit flat metrics and the five orientable manifolds admitting flat metrics with finite cyclic holonomy can be realized in the form \(\Gamma \setminus E(2)\) for some \(\Gamma \leq E(2)\) [27, Table 1]. In particular, the three-torus admits locally homogeneous metrics modeled on this geometry, some of which are not flat.

From the preceding discussion we deduce the following classification of metrically maximal three-dimensional geometries, which shows the universal Riemannian coverings of closed locally homogeneous three-manifolds come in eight families.

The Metrically Maximal Three-Dimensional Geometries. —

A metrically maximal three-dimensional geometry is equivalent to one of the following geometries:

- (MM1) the \(E(2)\)-geometry \((E(2), E(2))\);
- (MM2) the \(S^3\)-geometry \((S^3, S^3)\);
- (MM3) the \(H^3\)-geometry \((H^3, \text{Isom}(H^3)\circ)\);
- (MM4) the \(S^2 \times \mathbb{R}\)-geometry \((S^2 \times \mathbb{R}, \text{Isom}(S^2 \times \mathbb{R})\circ)\);
- (MM5) the \(H^2 \times \mathbb{R}\)-geometry \((H^2 \times \mathbb{R}, \text{Isom}(H^2 \times \mathbb{R})\circ)\);
- (MM6) the Nil-geometry \((\text{Nil}, \text{Nil})\);
- (MM7) the \(\text{SL}_2(\mathbb{R})\)-geometry \((\text{SL}_2(\mathbb{R}), \text{SL}_2(\mathbb{R})\)));
- (MM8) the \(\text{Sol}\)-geometry \((\text{Sol}, \text{Sol})\).
Equivalently, a compact locally homogeneous Riemannian three-manifold is modeled on one of the eight metrically maximal geometries above.

Therefore, in contrast with the two-dimensional case, the Thurston geometries (T3), (T4), (T5) and (T8) are the only symmetry maximal three-dimensional geometries that are also metrically maximal.

1.2. On the audibility of three-dimensional geometric structures

As we will recall in Section 2, the heat invariants associated to a closed Riemannian manifold \((M, g)\) form a sequence \(\{a_j(M, g)\}_{j=0}^\infty\) of spectral invariants, where, in theory, each \(a_j(M, g)\) can be expressed as an average of local geometric data. After observing the first four heat invariants of a locally homogeneous Riemannian three-manifold can (with a few possible exceptions) be expressed as symmetric polynomials in the eigenvalues of the associated Ricci tensor (see Theorem 2.18), we conduct an analysis that demonstrates that among compact locally homogeneous three-manifolds (1) a space modeled on the \(S^2 \times \mathbb{R}\)-geometry, \(\mathbb{H}^2 \times \mathbb{R}\)-geometry, Nil-geometry or \(E(2)\)-geometry is determined up to local isometry by its spectrum, (2) the property of being modeled on the \(S^3\)-geometry is audible and any Riemannian manifold modeled on the \(S^3\)-geometry that is sufficiently close to a metric of constant positive curvature is determined up to local isometry by its spectrum, (3) there is partial evidence that the property of being modeled on the metrically maximal geometry \((\text{SL}_2(\mathbb{R}), \text{SL}_2(\mathbb{R}))\) is audible, and (4) local geometry is audible among spaces modeled on the metrically maximal geometry \((\text{Sol}, \text{Sol})\). Specifically, we establish the following theorem, the consequences of which are discussed in the remainder of this subsection and summarized in Figure 1.2.

**Theorem 1.1.** — For \(j = 1, 2\), let \((M_j, g_j)\) be a compact locally homogeneous three-manifold with Ricci tensor \(\text{Ric}_j\) and corresponding vector of Ricci eigenvalues \(\nu(g_j) = (\nu_1(g_j), \nu_2(g_j), \nu_3(g_j))\). Now, suppose the first four heat invariants of \((M_1, g_1)\) and \((M_2, g_2)\) agree; i.e., \(a_j(M_1, g_1) = a_j(M_2, g_2)\), for \(j = 0, 1, 2, 3\).

1. Suppose \((M_1, g_1)\) is modeled on the \(S^2 \times \mathbb{R}\)-geometry, \(\mathbb{H}^2 \times \mathbb{R}\)-geometry, Nil-geometry or \(E(2)\)-geometry. Then, \((M_1, g_1)\) and \((M_2, g_2)\) are locally isometric; that is, \((M_1, g_1)\) and \((M_2, g_2)\) have a common universal Riemannian cover.
(2) Suppose \((M_1, g_1)\) is modeled on the \(S^3\)-geometry. Then, \((M_2, g_2)\) is also modeled on the \(S^3\)-geometry and \(\text{Ric}_1\) and \(\text{Ric}_2\) have the same signature (up to reordering of the Ricci eigenvalues). Furthermore, within the space of left-invariant metrics on \(S^3\), there is a neighborhood \(U\) of the round metric such that if the universal Riemannian cover of \((M_1, g_1)\) is isometric to a space in \(U\), then \((M_1, g_1)\) and \((M_2, g_2)\) are locally isometric.

(3) Suppose \((M_1, g_1)\) is modeled on the \(\widetilde{\text{SL}}_2(\mathbb{R})\)-geometry. Furthermore, assume (up to reordering of the Ricci eigenvalues) \(\text{Ric}_1\) has signature \((+, -, -)\) with \(P_2(\nu(g_1)) > 0\), where \(P_2\) is the second elementary symmetric polynomial in three variables. Then, \((M_2, g_2)\) is also modeled on the \(\widetilde{\text{SL}}_2(\mathbb{R})\)-geometry and (up to reordering of the Ricci eigenvalues) \(\text{Ric}_2\) also has signature \((+, -, -)\) with \(P_2(\nu(g_2)) > 0\). If, in addition, the quantity \(P_1(\nu(g_1))^2 - 4P_3(\nu(g_1))\) is negative, where \(P_1\) and \(P_2\) are the first and second elementary symmetric polynomials in three variables, then \((M_1, g_1)\) and \((M_2, g_2)\) are locally isometric.

(4) Suppose \((M_1, g_1)\) and \((M_2, g_2)\) are both modeled on the \(\text{Sol}\)-geometry, then \((M_1, g_1)\) and \((M_2, g_2)\) are locally isometric.

Combining the first statement of the preceding theorem with Berger’s observation that, among closed Riemannian three-manifolds, a closed three-manifold of constant sectional curvature is determined up to local isometry by its first three heat invariants [4, Theorem 7.1], we discover that the property of being locally symmetric is audible among compact locally homogeneous three-manifolds. In fact, each locally symmetric three-manifold is determined up to local isometry by its spectrum among all compact locally homogeneous three-manifolds, which is an optimal result due to the existence of pairs of isospectral locally symmetric three-manifolds with a common cover (see the discussion after Corollary 1.3). We also note that one can check that up to scaling the space of Riemannian metrics associated to the three-dimensional symmetry maximal geometry \((T7)\) forms a one-parameter family \(\{g_t\}_{t > 0}\) of left-invariant metrics on \(\widetilde{\text{SL}}_2(\mathbb{R})\), where the Ricci eigenvalues of \(g_t\) are \(\nu_1(g_t) = 2\) and \(\nu_2(g_t) = \nu_3(g_t) = -2(t + 1)\). It then follows from Theorem 1.1(3) that, among locally homogeneous three-manifolds, a space sharing the same first four heat invariants as a space modeled on the symmetry maximal geometry \((T7)\) must be modeled on the metrically maximal geometry \((\text{MM7})\). This discussion and the first two statements of Theorem 1.1 can be summarized as follows.

Figure 1.2. There are eight metrically maximal three-dimensional geometries upon which all compact locally homogeneous three-manifolds are modeled. This table summarizes the degree to which a three-dimensional compact geometric structure \((M, g)\) modeled on the metrically maximal geometry \((X, G)\) can be distinguished from other compact locally homogeneous three-manifolds via its spectrum. The results in (magenta) italicized print are proven in this article.

**Corollary 1.2.** — Among compact locally homogeneous three-manifolds, a compact three-manifold with universal Riemannian cover isometric to

1. a symmetric space,
2. \(E(2)\) equipped with a left-invariant metric,
3. Nil equipped with a left-invariant metric, or
4. \(S^3\) equipped with a left-invariant metric sufficiently close to a round metric

is determined up to local isometry by its first four heat invariants \(a_0, a_1, a_2\) and \(a_3\). Additionally, among compact locally homogeneous three-manifolds, a space sharing the same first four heat invariants as one modeled on the symmetry maximal geometry \((\widetilde{\text{SL}_2(\mathbb{R})}, \text{Isom}(\text{SL}_2(\mathbb{R}), g_{\text{max}})^o)\) must be modeled on the metrically maximal geometry \((\text{SL}_2(\mathbb{R}), \text{SL}_2(\mathbb{R}))\).

There are four closed three-manifolds admitting geometric structures modeled on \((S^2 \times \mathbb{R}, \text{Isom}(S^2 \times \mathbb{R})^o)\): namely, \(S^2 \times S^1\), \(\mathbb{R}P^2 \times S^1\), \(\mathbb{R}P^3 \# \mathbb{R}P^3\)
and the non-trivial $S^1$-bundle over $\mathbb{R}P^2$. And, each of these spaces possesses a two-dimensional family of locally symmetric metrics. In Section 4, we use the fundamental tone (i.e., the first non-zero eigenvalue of the Laplace operator) to show that the compact locally symmetric spaces modeled on $(S^2 \times \mathbb{R}, \text{Isom}(S^2 \times \mathbb{E})^o)$ can be mutually distinguished by their spectra (see Proposition 4.1). Combining this observation with the preceding corollary, we find that among compact locally homogeneous spaces, any closed Riemannian manifold modeled on $(S^2 \times \mathbb{R}, \text{Isom}(S^2 \times \mathbb{E})^o)$ is uniquely determined by its spectrum.

**Corollary 1.3.** — Among compact locally homogeneous three-manifolds, a compact locally symmetric three-manifold modeled on the metrically maximal geometry $(S^2 \times \mathbb{R}, \text{Isom}(S^2 \times \mathbb{E})^o)$ is determined up to isometry by its spectrum.

Therefore, up to scaling, the common Riemannian covering of a non-trivial isospectral pair of compact locally symmetric three-manifolds must be $\mathbb{E}^3$, $\mathbb{H}^3$ or $\mathbb{H}^2 \times \mathbb{E}$, and such isospectral pairs exist. Indeed, we note that while the flat three-dimensional tori can be mutually distinguished by their spectra [32], $\mathbb{E}^3$ covers a unique isospectral pair known as “tetra and didi” [10, 29]. In contrast, the literature contains numerous examples of isospectral pairs covered by $\mathbb{H}^3$ or $\mathbb{H}^2 \times \mathbb{E}$ [8, 28, 39, 45].

Focusing on nilmanifolds, we recall that by explicitly computing the spectra of three-dimensional Riemannian nilmanifolds, Gordon and Wilson have shown that compact three-manifolds modeled on the Nil-geometry can be mutually distinguished via their spectra [16]. Applying Theorem 1.1, it follows that three-dimensional Riemannian nilmanifolds are determined up to isometry by their spectra among compact locally homogeneous three-manifolds.

**Corollary 1.4.** — Among compact locally homogeneous three-manifolds, a compact locally homogeneous three-manifold modeled on the metrically maximal geometry $(\text{Nil}, \text{Nil})$ is determined up to isometry by its spectrum.

There are infinitely many closed manifolds admitting geometric structures modeled on $(\text{Nil}, \text{Nil})$ including Dehn-twisted torus bundles (see Figure 1.3).

We conclude this section by noting that Ikeda has shown that any closed three-manifold of constant positive sectional curvature (i.e., a closed manifold modeled on $(S^3, \text{Isom}(S^3)^o)$) is uniquely determined by its spectrum among all Riemannian manifolds [19]. Corollaries 1.3 and 1.4 provide strong
evidence that the same is likely true for any closed Riemannian three-manifold modeled on \((S^2 \times \mathbb{R}, \text{Isom}(S^2 \times \mathbb{E})^o)\) or \((\text{Nil}, \text{Nil})\).

1.3. Can you hear the local geometry of a three-manifold?

The results presented in this article and its sequel [21] provide strong evidence that one should expect a compact locally homogeneous three-manifold to be determined up to local isometry by its spectrum. The broader question undergirding this article is whether the local geometry of any low-dimensional closed Riemannian manifold is encoded in its spectrum.

Indeed, the earliest examples of isospectral Riemannian manifolds all have a common Riemannian covering. For example, isospectral pairs arising from the original incarnation of Sunada’s method necessarily have a common Riemannian covering [39]. This coupled with the fact that the heat invariants are averages of local geometric data makes it seem plausible that the universal Riemannian cover of a closed Riemannian manifold is audible. However, as we noted previously, in 1993, Carolyn Gordon produced the first examples of closed isospectral manifolds that are not locally isometric [13, 14] via a construction inspired by Szabo’s approach to building
isospectral, yet locally non-isometric manifolds with boundary [41]. The ensuing years have seen many more examples of isospectral, yet locally non-isometric closed manifolds [26, 33, 35], including surprising pairs arising from the third named author’s generalization of Sunada’s method [1, 40]. And, in 2001, Schueth’s examples of isospectral metrics on $S^2 \times T^2$ [34] demonstrated that the local geometry of a closed Riemannian manifold of dimension at least four need not be encoded in its spectrum, leaving open the following problem.

**Problem B.** — *Is the isometry class of the universal Riemannian cover of a closed Riemannian manifold of dimension two or three “audible”?*

**Structure of the Paper**

In Section 2, we first review the formulae for the first four heat invariants of a Riemannian manifold. Then, with a few exceptions, we find the first four heat invariants of a compact locally homogeneous three-manifold can be expressed as the product of its volume with a symmetric rational function of the eigenvalues of the accompanying Ricci tensor. The main goal of the section is to establish Theorem 2.22, which severely restricts the possible Ricci-eigenvalues possessed by isospectral three-manifolds with Riemannian universal cover isometric to a unimodular Lie group equipped with a left-invariant metric. Theorem 2.22 is then used alongside Proposition 3.8, in Section 3, to prove Theorem 1.1, which describes audibility results concerning various three-dimensional geometries. Finally, in Section 4, we let $S^n_k$ denote the round $n$-sphere of constant sectional curvature $k > 0$ and compute the Laplace spectra of manifolds having universal Riemannian cover $S^n_k \times E$. Then, by applying Theorem 1.1 and comparing fundamental tones, we show that Riemannian manifolds modeled on the $S^2 \times \mathbb{R}$-geometry are determined up to isometry by their Laplace spectra among compact locally homogeneous three-manifolds.

**Acknowledgments**

The authors thank Dorothee Schueth for helpful suggestions regarding a previous draft of this article; especially, bringing our attention to

---

(3) Szabo discovered his examples prior to Gordon’s 1993 paper, but his result remained unpublished until 1999.
Lemma 3.7 and Proposition 3.8. We thank Steve Trettel for providing the stunning color images of the $\mathbb{H}^3$ and Nil geometries used in the introduction (see Figures 1.1 and 1.3). The reader is encouraged to visit http://www.3-dimensional.space to explore more visualizations of the Thurston geometries by Remi Coulon, Subeta Matsumoto, Henry Sagerman and Steve Trettel. The authors are grateful to Jean-François Lafont for his assistance with translating the title, abstract and keywords of this article into French. Finally, we appreciate the referee’s careful reading of the manuscript and their helpful feedback.

2. Heat invariants and locally homogeneous three-manifolds

In this section we will review the heat invariants – the main analytical tool in this article – and derive computational simplifications that occur when considering locally homogeneous three-manifolds. Of particular interest to us will be the fact that the heat invariants of a locally homogeneous three-manifold covered by a unimodular Lie group are almost symmetric functions in the sectional curvatures $K_{12}$, $K_{13}$ and $K_{23}$ determined by a choice of Milnor frame (see Definition 2.6). This will allow us to express the heat invariants of a locally homogeneous three-manifold as a symmetric function of the Ricci-eigenvalues.

2.1. The heat invariants

The Laplace–Beltrami operator of a closed and connected Riemannian n-manifold $(M, g)$ is the (essentially) self-adjoint operator $\Delta_g = -\text{div} \circ \text{grad}_g$ on $L^2(M, \nu_g)$. The sequence $\lambda_0 = 0 < \lambda_1 \leq \lambda_2 \leq \cdots \nearrow \infty$ of eigenvalues of $\Delta_g$, repeated according to multiplicity, is the spectrum of $(M, g)$ and we will say that two manifolds are isospectral when their spectra agree. Letting $\{\phi_k\}$ be an orthonormal basis of $L^2(M, \nu_g)$ consisting of $\Delta_g$-eigenfunctions, then for each $t > 0$ we may define $e^{-t\Delta_g} : L^2(M, \nu_g) \to L^2(M, \nu_g)$ to be the linear extension of $e^{-t\lambda_k}\phi_k = e^{-t\lambda_k}\phi_k$. Then, $\{e^{-t\Delta_g}\}_{t>0}$ is a family of self-adjoint operators known as the heat semi-group.

The operators forming the heat semi-group are trace class (cf. [3, Theorem V.3]) and we have the following asymptotic expansion for the trace of the heat semi-group [23]:

$$\text{Tr}(e^{-t\Delta_g}) = \sum_{k=0}^{\infty} e^{-t\lambda_j} \sim 0 \left(4\pi t\right)^{-n/2} \sum_{m=0}^{\infty} a_m(M, g)t^m.$$
The coefficients $\{a_m(M, g)\}_{m=0}^{\infty}$ in this expression are the heat invariants of $(M, g)$ and they are spectral invariants; i.e., isospectral manifolds have equal heat invariants. There are universal polynomials $u_m(M, g)$ in the components of the curvature tensor and its covariant derivatives, such that $a_m(M, g) = \int_M u_m(M, g) \, d\nu_g$ [3, p. 145] or [31, Chapter VI.5]. Explicit formulae for the heat invariants are known in only a few cases (cf. [25]).

Let $\nabla, R = (R_{ijkl}), \operatorname{Ric} = (\rho_{jl} = R^i_{jil}), \operatorname{Scal} = (g^{ij}\rho_{ij})$, and $\nu_g$ denote the Levi–Civita connection, Riemannian curvature tensor, Ricci curvature tensor, scalar curvature, and Riemannian density, respectively. We follow the sign convention for the curvature tensor in [42] and [30]; namely, for smooth vector fields $X, Y, Z$ on $M$

\begin{equation}
R(X, Y)Z = \nabla_{[X,Y]}Z - [\nabla_X, \nabla_Y]Z.
\end{equation}

Consequently, the sectional curvature of the plane spanned by two orthogonal unit vectors $X, Y \in T_pM$ is given by $R(X, Y, X, Y)$. The first four heat invariants are given by ([43]):

\begin{enumerate}
\item[(2.2)] $a_0(M, g) = \operatorname{vol}(M, g) = \int_M 1 \, d\nu_g$
\item[(2.3)] $a_1(M, g) = \frac{1}{6} \int_M \operatorname{Scal} \, d\nu_g$,
\item[(2.4)] $a_2(M, g) = \frac{1}{360} \int_M 2(|R|^2 - |\operatorname{Ric}|^2) + 5 \operatorname{Scal}^2 \, d\nu_g$,
\end{enumerate}

and

\begin{enumerate}
\item[(2.5)] $a_3(M, g) = \frac{1}{6!} \int_M \left( \overline{D} + \overline{A} + \frac{2}{3} \operatorname{Scal}(|R|^2 - |\operatorname{Ric}|^2) + \frac{5}{9} \operatorname{Scal}^3 \right) \, d\nu_g$,
\end{enumerate}

where $\overline{D}$ is defined by

\begin{equation}
\overline{D} = -\frac{1}{9} |\nabla R|^2 - \frac{26}{63} |\nabla \operatorname{Ric}|^2 - \frac{142}{63} |\nabla \operatorname{Scal}|^2,
\end{equation}

and $\overline{A}$ is defined by

\begin{equation}
\overline{A} = \frac{8}{21} (R, R, R) - \frac{8}{63} (\operatorname{Ric}; R, R) + \frac{20}{63} (\operatorname{Ric}; \operatorname{Ric}; R) - \frac{4}{7} (\operatorname{Ric} \operatorname{Ric} \operatorname{Ric}),
\end{equation}

TOME 0 (0), FASCICULE 0
where, for tensor fields $P = (P_{ijkl}), Q = (Q_{ijkl}), T = (T_{ijkl}), U = (U_{ij}), V = (V_{ij}),$ and $W = (W_{ij})$ on $(M, g),$ we have the following products
\begin{equation}
(P, Q) = P_{ijkl}Q^{ijkl}, \tag{2.8}
\end{equation}
\begin{equation}
|P|^2 = (P, P), \tag{2.9}
\end{equation}
\begin{equation}
(P, Q, T) = P_{ijkl}Q_{rs}T_{ij}^{rs}, \tag{2.10}
\end{equation}
\begin{equation}
(U, Q, T) = U_{rs}Q_{rjkl}T_{ij}^{s}, \tag{2.11}
\end{equation}
\begin{equation}
(U; V, T) = U^{ab}V^{cd}T_{abcd}, \tag{2.12}
\end{equation}
\begin{equation}
(UVW) = U_{j}^{i}V_{k}^{j}W_{i}^{k}. \tag{2.13}
\end{equation}

Remark 2.1.— For $j = 1, 2,$ let $(M_j, g_j)$ be a Riemannian manifold with tensor fields $P_j, Q_j, T_j, U_j, V_j$ and $W_j$ as above, and let $P = P_1 + P_2, T = T_1 + T_2, Q = Q_1 + Q_2, U = U_1 + U_2, V = V_1 + V_2$ and $W = W_1 + W_2$ be their orthogonal sums on the product manifold $(M_1 \times M_2, g_1 \times g_2).$ Then, $(P, Q) = \sum (P_j, Q_j), (P, Q, T) = \sum (P_j, Q_j, T_j), (U; Q, T) = \sum (U_j; Q_j, T_j),$ $(U; V, T) = \sum (U_j; V_j; T_j)$ and $(UVW) = \sum (U_j V_j W_j).

Remark 2.2.— When $(M, g)$ is locally homogeneous, $\text{Scal}$ is constant, which implies \( \overline{\text{D}} = -\frac{1}{6} |\nabla R|^2 - \frac{26}{45} |\nabla \text{Ric}|^2. \) Furthermore, when $(M, g)$ is locally symmetric $\overline{\text{D}}$ is identically zero, since $\nabla R$ and $\nabla \text{Ric}$ both vanish.

The heat invariants have been used to prove many interesting spectral rigidity results. For instance, we have the following theorem demonstrating that constant curvature is an audible property in low dimensions.

**Theorem 2.3** (Berger [4], Tanno [42]). — Let $(M, g)$ and $(M', g')$ be compact manifolds of dimension $2 \leq n \leq 5$ such that $a_j(M, g) = a_j(M', g')$ for $j = 0, 1, 2, 3.$ And, fix a real number $K.$ Then, $(M, g)$ is a space of constant sectional curvature $K$ if and only if $(M', g')$ is a space of constant sectional curvature $K.$

In the case where the dimension is two or three, this theorem was observed to be true by Berger under the milder assumption that only the first three heat invariants agree [4, Theorem 7.1].

### 2.2. The geometry of locally homogeneous three-manifolds.

We begin by recalling the following well-known fact.

**Lemma 2.4.** — Let $(M, g)$ be a Riemannian manifold and, for $p \in M,$ let $\{e_1, \ldots, e_n\}$ be an orthonormal basis of $T_p M.$ If $\langle R(e_i, e_j) e_k, e_l \rangle = 0$
whenever three of the indices are pairwise distinct, then \( \{e_1, \ldots, e_n\} \) diagonalizes the Ricci tensor \( \text{Ric}(\cdot) \). And, the converse is true when \( M \) is three-dimensional.

Recall that the simply-connected and connected unimodular three-dimensional Lie groups are \( \mathbb{R}^3, S^3, \widehat{\text{SL}_2(\mathbb{R})}, \text{Nil}, \text{Sol} \) and \( E(2) \). The next result can be deduced easily from [22].

**Lemma 2.5.** — Let \( G \) be one of the six simply-connected three-dimensional unimodular Lie groups. Given a three-manifold \( (M,g) \) locally isometric to \( G \) equipped with a left-invariant metric, any orthonormal basis \( \{e_1, e_2, e_3\} \) of \( T_pM \) consisting of Ric-eigenvectors extends to a local framing \( \{E_1, E_2, E_3\} \) on a neighborhood \( U \) of \( p \) such that

1. \( \{E_1, E_2, E_3\} \) is orthonormal;
2. there are constants \( \lambda_1, \lambda_2 \) and \( \lambda_3 \) such that
   \[
   [E_1, E_2] = \lambda_3 E_3, \quad [E_2, E_3] = \lambda_1 E_1, \quad \text{and} \quad [E_3, E_1] = \lambda_2 E_2;
   \]
3. \( \{E_1, E_2, E_3\} \) diagonalizes the Ricci tensor:
   \[
   \text{Ric}(E_1) \equiv \nu_1 = 2\mu_2\mu_3, \quad \text{Ric}(E_2) \equiv \nu_2 = 2\mu_1\mu_3, \quad \text{and} \quad \text{Ric}(E_3) \equiv \nu_3 = 2\mu_1\mu_2,
   \]
   where \( \mu_i \equiv \frac{1}{2}(\lambda_1 + \lambda_2 + \lambda_3) - \lambda_i \) for \( i = 1, 2, 3 \).
4. \( R(E_i, E_j, E_k, E_l) \) and \( \text{Ric}(E_i, E_j) \) are constant for all choices of \( i, j, k \) and \( l \).

**Definition 2.6.** — Let \( (M,g) \) be a locally homogeneous three-manifold locally isometric to a unimodular Lie group \( G \) equipped with a left-invariant metric. And, let \( \{e_1, e_2, e_3\} \) be an orthonormal basis of \( T_pM \) consisting of eigenvectors of the Ricci tensor, for some \( p \in M \). An extension \( \{E_1, E_2, E_3\} \) of \( \{e_1, e_2, e_3\} \) to a neighborhood \( U \) of \( p \) as in Lemma 2.5 will be called a Milnor frame.

**Corollary 2.7.** — Let \( (M,g) \) be a locally homogeneous three-manifold locally isometric to a unimodular Lie group \( G \) equipped with a left-invariant metric and let \( \{E_1, E_2, E_3\} \) be a Milnor frame in a neighborhood of some \( p \in M \). Then,

1. \( \nabla_{E_j} E_j = 0 \) for \( j = 1, 2, 3 \);
2. \( \mu_1 = \Gamma^3_{12} = -\Gamma^2_{13}, \quad \mu_2 = \Gamma^1_{23} = -\Gamma^3_{21} \) and \( \mu_3 = \Gamma^2_{31} = -\Gamma^1_{32} \);
3. \( \nabla_{E_{\sigma(1)}} E_{\sigma(2)} = \Gamma^\sigma_{\sigma(1)\sigma(2)} E_{\sigma(3)} \), where \( \sigma \) is a cyclic permutation.
Remark 2.8. — Lemma 2.5 and Corollary 2.7 will be useful in Proposition 2.16 where we compute expressions for $|\nabla R|^2$ and $|\nabla \text{Ric}|^2$ for a locally homogeneous three-manifold modeled on a unimodular Lie group equipped with a left-invariant metric.

The constants $\lambda_1$, $\lambda_2$ and $\lambda_3$ in Lemma 2.5 are known as the structure constants. Milnor showed the three-dimensional unimodular Lie groups can be classified according to the sign (plus, minus, or zero) of these structure constants [22, Section 4]. Milnor also made the following observation concerning the signature of the Ricci tensor of left-invariant metrics on the non-abelian unimodular Lie groups.

**Lemma 2.9** ([22, Section 4]). — Let $(G, g)$ be a simply-connected three-dimensional non-abelian unimodular Lie group equipped with a left-invariant metric $g$, and let $\text{Ric}$ denote its associated Ricci tensor.

1. If $G = S^3$, then (up to a reordering of the Ricci eigenvalues) the signature of $\text{Ric}$ is $(+, +, +)$, $(+, 0, 0)$, or $(+, -,-)$, and all such signatures occur.
2. If $G = \text{Nil}$, then (up to a reordering of the Ricci eigenvalues) the signature of $\text{Ric}$ is $(+,-,-)$ and the scalar curvature is strictly negative.
3. If $G$ is $\text{SL}(2, \mathbb{R})$ or $\text{Sol}$, then (up to a reordering of the Ricci eigenvalues) the signature of $\text{Ric}$ is $(+,-,-)$ or $(0,0,-)$ and the scalar curvature is always negative.
4. If $G$ is $\text{E}(2)$, then $G$ admits a flat left-invariant metric and (up to reordering of the Ricci eigenvalues) every non-flat left-invariant metric on $G$ has Ricci signature $(+, -,-)$ and negative scalar curvature.

Since each three-dimensional non-abelian unimodular Lie group supports a left-invariant metric possessing a Ricci tensor of signature $(+, -,-)$, the three-dimensional non-abelian unimodular Lie groups cannot be distinguished through the signatures of the Ricci tensors of their respective left-invariant metrics. However, the following lemma allows us to deduce that from the eigenvalues of the Ricci tensor one may recover the model geometry of a three-dimensional manifold locally isometric to a non-abelian Lie group equipped with a left-invariant metric.

**Lemma 2.10.** — Let $(M, g)$ be a compact locally homogeneous three-manifold modeled on the geometry $(G, G)$, where $G$ is a three-dimensional non-abelian simply-connected unimodular Lie group. Suppose further that
the signature of the Ricci tensor of \((M, g)\) is \((+, -, -)\), where without loss of generality, we assume that \(\nu_1 > 0 > \nu_2 \geq \nu_3\). Then, \(G\) is

1. \(S^3\) if and only if \(\nu_1 > |\nu_3|\),
2. \(\text{SL}(2, \mathbb{R})\) if and only if \(\nu_1 < |\nu_2|\) or \(\nu_2 < |\nu_3|\),
3. \(\text{Sol}\) if and only if \(\nu_1 = |\nu_2| < |\nu_3|\),
4. \(E(2)\) if and only if \(\nu_1 = |\nu_3| > |\nu_2|\), and
5. \(\text{Nil}\) if and only if \(\nu_1 = |\nu_2| = |\nu_3|\).

**Remark 2.11.** — It follows from Lemma 3.4 that the components of any \(\nu = (\nu_1, \nu_2, \nu_3) \in \mathbb{R}^3\) satisfying \(\nu_1 > 0 > \nu_2 \geq \nu_3\) are the eigenvalues of a left-invariant metric on a unimodular Lie group \(G\).

**Proof of Lemma 2.10.** — The signs of \(\nu_1, \nu_2, \nu_3\) imply that the signs of \((\mu_1, \mu_2, \mu_3)\) are either \((- , + , +)\) or \((+, - , -)\).

When the signs of \((\mu_1, \mu_2, \mu_3)\) are \((+, - , -)\), we find

\[
\lambda_1 = \left(\frac{\nu_1 \nu_3}{2 \nu_2}\right)^{1/2} + \left(\frac{\nu_1 \nu_2}{2 \nu_3}\right)^{1/2},
\]

\[
\lambda_2 = -\left(\frac{\nu_2 \nu_3}{2 \nu_1}\right)^{1/2} + \left(\frac{\nu_1 \nu_2}{2 \nu_3}\right)^{1/2},
\]

and

\[
\lambda_3 = -\left(\frac{\nu_2 \nu_3}{2 \nu_1}\right)^{1/2} + \left(\frac{\nu_1 \nu_3}{2 \nu_2}\right)^{1/2}.
\]

The equation (2.14) implies that \(\lambda_1 > 0\). The lemma now follows by the classification of unimodular three-dimensional Lie groups in terms of the signs of \(\lambda_1, \lambda_2, \lambda_3\) (see [22, p. 307]).

The proof for the case when \((\mu_1, \mu_2, \mu_3) = (-, + , +)\) is similar.

**Definition 2.12.** — A multiset in \(\mathbb{R}\) is a map \(m : \mathbb{R} \to \mathbb{N} \cup \{0\}\), where we think of \(m(x)\) as the multiplicity of \(x\) in the multiset. A multiset \(m\) is said to be a \(k\)-multiset, for \(k \in \mathbb{N}\), if \(m\) is non-zero at finitely many distinct values \(x_1, \ldots, x_q\) and \(\sum m(x_j) = k\). A \(k\)-multiset \(m\) will be denoted by \([x_{11}, \ldots, x_{1m(1)}], \ldots, x_{q1}, \ldots, x_{qm(q)}]\), where \(x_{ij} = x_i\) for \(j = 1, \ldots, m(x_i)\). The collection of \(k\)-multisets consisting of positive numbers will be denoted by \(\mathcal{M}_k^+\).

The following proposition shows that among spaces locally isometric to a non-abelian Lie group equipped with a left-invariant metric, the multiset of Ricci eigenvalues determines the model geometry.

**Proposition 2.13.** — For \(j = 1, 2\), let \((M_j, g_j)\) be a locally homogeneous three-manifold modeled on the geometry \((G_j, G_j)\), where \(G_j\) is a
simply-connected unimodular Lie group, and let $\text{Ric}_j$ be the associated Ricci tensor with eigenvalues $\nu_1(g_j), \nu_2(g_j)$ and $\nu_3(g_j)$. If

$$[\nu_1(g_1), \nu_2(g_1), \nu_3(g_1)] = [\nu_1(g_2), \nu_2(g_2), \nu_3(g_2)],$$

then $G_1$ and $G_2$ are isomorphic Lie groups.

Proof. — Follows directly from Lemmas 2.9 and 2.10. □

The previous proposition suggests that a possible strategy for recovering model geometries from spectral data is to recover the Ricci eigenvalues from the heat invariants or other spectral invariants. In the next section we lay the groundwork for this plan.

### 2.3. Heat invariants of locally homogeneous three-manifolds.

In this section we will discover that the heat invariants $a_1, a_2$ and $a_3$ of a compact locally homogeneous three-manifold can be expressed as symmetric functions in the eigenvalues of the Ricci tensor with respect to a Milnor frame. These expressions will be key to our arguments. We begin with an observation regarding any three-manifold.

**Proposition 2.14.** — Let $(M, g)$ be a Riemannian three-manifold and let $\{E_1, E_2, E_3\}$ be a local orthonormal framing on a neighborhood $U$ of $p \in M$ that diagonalizes Ricci. Then, letting $K_{ij}(q) \equiv \text{Sec}(E_{iq}, E_{jq})$ for $1 \leq i < j \leq 3$, we have the following expressions on $U$:

\[
\text{Scal} = 2\{K_{12} + K_{13} + K_{23}\},
\]

\[
|R|^2 = 4\{(K_{12})^2 + (K_{13})^2 + (K_{23})^2\},
\]

\[
|Ric|^2 = (K_{12} + K_{13})^2 + (K_{12} + K_{23})^2 + (K_{13} + K_{23})^2,
\]

\[
(R, R, R) = 8\{(K_{12})^3 + (K_{13})^3 + (K_{23})^3\},
\]

\[
(R; R, R) = 2\{(K_{12} + K_{13})(K_{12})^2 + (K_{13})^2\}
+ (K_{12} + K_{23})(K_{12})^2 + (K_{23})^2
+ (K_{13} + K_{23})(K_{13})^2 + (K_{23})^2\},
\]

\[
(R; Ric; R) = 2\{K_{12}(K_{12} + K_{13})(K_{12} + K_{23})
+ K_{13}(K_{12} + K_{13})(K_{13} + K_{23})
+ K_{23}(K_{12} + K_{23})(K_{13} + K_{23})\},
\]

\[
(Ric; Ric; Ric) = (K_{12} + K_{13})^3 + (K_{12} + K_{23})^3 + (K_{13} + K_{23})^3.
\]

Proof. — A long, yet straightforward computation relying on the chosen frame. □
Remark 2.15. — It follows that for a three-manifold \((M, g)\) the integrand of each of the heat invariants \(a_0(M, g)\), \(a_1(M, g)\) and \(a_2(M, g)\) can be expressed locally as a symmetric polynomial in the principal curvatures.

For the remainder of the paper we will let \(P_1(x, y, z)\), \(P_2(x, y, z)\) and \(P_3(x, y, z)\) be the elementary symmetric polynomials in three variables:

\[
P_1(x, y, z) = x + y + z, \quad P_2(x, y, z) = xy + xz + yz, \quad \text{and} \quad P_3(x, y, z) = xyz.
\]

Proposition 2.16. — Let \((M, g)\) be a locally homogeneous three-manifold locally isometric to a unimodular Lie group \(G\) equipped with a left-invariant metric. Let \(\{E_1, E_2, E_3\}\) be a Milnor frame (see Definition 2.6), \(K_{ij} \equiv \text{Sec}(E_i, E_j)\) for \(1 \leq i < j \leq 3\) and \(\Gamma_{ij}^k \equiv \langle \nabla_{E_i} E_j, E_k \rangle\). Then, we have the following expressions:

\[
K_{\sigma(1)\sigma(2)} = \frac{1}{2} \left( P_1(\nu_1, \nu_2, \nu_3) - 2 \nu_{\sigma(3)} \right),
\]

where \(\sigma\) is any permutation on three elements,

\[
- \frac{14}{3} \tilde{D} = 4|\nabla \text{Ric}|^2 = |\nabla R|^2,
\]

and

\[
|\nabla R|^2 = 8 \{ (\Gamma_{12}^3 K_{13} + \Gamma_{13}^2 K_{12})^2 + (\Gamma_{21}^3 K_{23} + \Gamma_{23}^1 K_{12})^2
\]

\[
+ (\Gamma_{31}^2 K_{23} + \Gamma_{32}^1 K_{13})^2 \}.
\]

Proof. — A long, yet straightforward computation relying on Lemma 2.5 and Corollary 2.7.

Corollary 2.17. — Let \((M, g)\) be a locally homogeneous three-manifold. Fix \(p \in M\) and let \(\{e_1, e_2, e_3\}\) be an orthonormal basis of \(T_p M\) consisting of eigenvectors for the Ricci tensor with associated eigenvalues \(\nu = (\nu_1, \nu_2, \nu_3)\). Let \(K_{12} = R(e_1, e_2, e_1, e_2)\), \(K_{13} = R(e_1, e_3, e_1, e_3)\) and \(K_{23} = R(e_2, e_3, e_2, e_3)\) be the associated principal curvatures.

(1) Then, we have the following relationship between the principal curvatures and the eigenvalues of the Ricci tensor:

\[
\begin{pmatrix}
K_{12} \\
K_{13} \\
K_{23}
\end{pmatrix} = \frac{1}{2} \begin{pmatrix}
-1 & 1 & 1 \\
1 & -1 & 1 \\
1 & 1 & -1
\end{pmatrix} \begin{pmatrix}
\nu_3 \\
\nu_2 \\
\nu_1
\end{pmatrix},
\]
and we have the following expressions:

(2.28) \[ \text{Scal} = P_1(\nu), \]
(2.29) \[ |R|^2 = 3P_1^2(\nu) - 8P_2(\nu), \]
(2.30) \[ |\text{Ric}|^2 = P_1^2(\nu) - 2P_2(\nu), \]
(2.31) \[ (R, R, R) = P_1^3(\nu) - 24P_3(\nu), \]
(2.32) \[ (\text{Ric}; R, R) = -6P_3(\nu) + P_1^3(\nu) - 2P_1(\nu)P_2(\nu), \]
(2.33) \[ (\text{Ric}; \text{Ric}; R) = P_1(\nu)P_2(\nu) - 6P_3(\nu), \]
(2.34) \[ (\text{Ric Ric Ric}) = 3P_3(\nu) + P_1^3(\nu) - 3P_1(\nu)P_2(\nu), \]
(2.35) \[ A = \frac{16}{63} \left( -\frac{10}{8} P_1^3(\nu) - \frac{189}{4} P_3(\nu) + 9P_1(\nu)P_2(\nu) \right), \]
(2.36) \[ \bar{A} + \frac{2}{3} \text{Scal}(|R|^2 - |\text{Ric}|^2) + \frac{5}{9} \text{Scal}^3 \]
\[ = \frac{11}{7} P_1^3(\nu) - 12P_3(\nu) - \frac{12}{7} P_1(\nu)P_2(\nu). \]

(2) Now, assume that \((M, g)\) is modeled on a unimodular Lie group equipped with a left-invariant metric for which \(P_3(\nu) \neq 0\); i.e., all the Ricci eigenvalues are non-zero. Then, we have the following expressions for terms in the integrand of the heat invariants involving the covariant derivatives:

(2.37) \[ |\nabla R|^2 = -36P_3(\nu) + 40P_1(\nu)P_2(\nu) - 8P_1^3(\nu) \]
\[ + 4 \left( \frac{P_2^2(\nu)P_2^2(\nu) - 4P_1^3(\nu)}{P_3(\nu)} \right), \]
and

(2.38) \[ D = \frac{54}{7} P_3(\nu) - \frac{60}{7} P_1(\nu)P_2(\nu) + \frac{12}{7} P_1^3(\nu) \]
\[ - \frac{6}{7} \left( \frac{P_2^2(\nu)P_2^2(\nu) - 4P_1^3(\nu)}{P_3(\nu)} \right). \]

The previous two propositions combine to give us the following expressions for the heat invariants of a locally homogeneous three-manifold as symmetric functions in the eigenvalues of the Ricci tensor.

**Theorem 2.18.** — Let \((M, g)\) be a locally homogeneous three-manifold and let \(\nu = (\nu_1, \nu_2, \nu_3)\) be the eigenvalues of the associated Ricci tensor. Then, the heat invariants may be computed in terms of the Ricci eigenvalues as follows:

(2.39) \[ a_1(M, g) = \frac{a_0(M, g)}{6} P_1(\nu) \]
and
\[(2.40) \quad a_2(M, g) = \frac{a_0(M, g)}{360} (9P_1^2(\nu) - 12P_2(\nu)) .\]

If, in addition, \((M, g)\) is covered by a unimodular Lie group equipped with a left-invariant metric for which all eigenvalues of the Ricci tensor are non-zero, then
\[(2.41) \quad a_3(M, g) = \frac{a_0(M, g)}{7!} \times \left( 23P_1^3(\nu) - 30P_3(\nu) - 72P_1(\nu)P_2(\nu) - \frac{6P_2^2(\nu)P_2(\nu) - 24P_3^2(\nu)}{P_3(\nu)} \right) .\]

Remark 2.19. — In the sequel to this article [21], which concentrates on elliptic three-manifolds, we will find it advantageous to express the heat invariants as symmetric functions of the Christoffel symbols rather than the Ricci eigenvalues.

Definition 2.20. — Let \((M, g)\) be a locally homogeneous three-manifold with associated Ricci eigenvalues \(\nu(g) = (\nu_1(g), \nu_2(g), \nu_3(g))\). Then, we may define
\[
\begin{align*}
b_0(M, g) &\equiv a_0(M, g) \\
b_1(M, g) &= P_1(\nu(g)) \\
b_2(M, g) &= P_2(\nu(g)) .
\end{align*}
\]
In the event that \((M, g)\) is locally isometric to a unimodular Lie group equipped with a left-invariant metric such that \(P_3(\nu(g)) \neq 0\) (i.e., it is positive), then we also define
\[
b_3(M, g) = 30P_3(\nu(g)) + \frac{6P_2^2(\nu(g))P_2(\nu(g)) - 24P_3^2(\nu(g))}{P_3(\nu(g))} .
\]

The previous theorem shows us that the constants \(b_j(M, g)\) \(j = 0, 1, 2, 3\) form a collection of spectral invariants among locally homogeneous three-manifolds.

Corollary 2.21. — Let \((M, g)\) and \((M', g')\) be locally homogeneous three-manifolds.

1. \(a_j(M, g) = a_j(M', g')\) for \(j = 0, 1, 2\) if and only if \(b_j(M, g) = b_j(M', g')\) for \(j = 0, 1, 2\).

2. Additionally, if \((M, g)\) and \((M', g')\) are each modeled on unimodular Lie groups outfitted with left-invariant metrics such that \(P_3(\nu(g)), P_3(\nu(g')) \neq 0\),
then \( a_j(M, g) = a_j(M', g') \) for \( j = 0, 1, 2, 3 \) if and only if \( b_j(M, g) = b_j(M', g') \) for \( j = 0, 1, 2, 3 \).

**Theorem 2.22.** — Let \((M, g)\) and \((M', g')\) be compact locally homogeneous three-manifolds where the universal Riemannian covering of each is isometric to a simply-connected non-abelian unimodular Lie group equipped with a left-invariant metric (i.e., each is modeled on one of the metrically maximal geometries \((\text{MM1}), (\text{MM2}), (\text{MM6}), (\text{MM7})\) or \((\text{MM8})\)) and assume further that the eigenvalues of \(\text{Ric}(g)\) and \(\text{Ric}(g')\) are all non-zero. If \(a_j(M, g) = a_j(M', g')\) for \(j = 0, 1, 2, 3\), then

\[
P_3(\nu(g')) = P_3(\nu(g))
\]

or

\[
P_3(\nu(g')) = C(M, g) = \frac{6P_1^2(\nu(g))P_2(\nu(g)) - 24P_2^3(\nu(g))}{30P_3(\nu(g))}.
\]

**Proof.** — The assumption concerning the heat invariants is equivalent to \(b_j(M, g) = b_j(M', g')\) for \(j = 0, 1, 2, 3\). From which we deduce

\[
30P_3(\nu(g)) + \frac{6P_1^2(\nu(g))P_2(\nu(g)) - 24P_2^3(\nu(g))}{P_3(\nu(g))}
\]

\[
= 30P_3(\nu(g')) + \frac{6P_1^2(\nu(g'))P_2(\nu(g')) - 24P_2^3(\nu(g'))}{P_3(\nu(g'))},
\]

which has the claimed solutions. 

\[\square\]

3. Can you hear three-dimensional geometric structures?

The goal of this section is to establish Theorem 1.1. We will proceed in steps, but first we will collect a few useful observations.

**Lemma 3.1.** — Fix real numbers \( \alpha, \beta \) and \( \gamma \). Then, the multiset \([\alpha, \beta, \gamma]\) determines and is determined by the triple

\[
(P_1(\alpha, \beta, \gamma), P_2(\alpha, \beta, \gamma), P_3(\alpha, \beta, \gamma)),
\]

where \(P_j\) is the \(j\)-th symmetric polynomial in three variables.

**Proof.** — This follows immediately from the equation

\[
(x + \alpha)(x + \beta)(x + \gamma) = x^3 + P_1(\alpha, \beta, \gamma)x^2 + P_2(\alpha, \beta, \gamma)x + P_3(\alpha, \beta, \gamma).
\]

\[\square\]
Lemma 3.2 ([22, Corollary 4.4]). — Let \((M,g)\) be a three-dimensional manifold modeled on a unimodular Lie group equipped with a left-invariant metric. Then, \(P_3(\nu(g)) \geq 0\). That is, the product of the Ricci eigenvalues of \((M,g)\) is nonnegative. Furthermore, equality happens if and only if at least two of the principal Ricci curvatures are zero.

Lemma 3.3. — Let \((M,g)\) be a locally homogeneous three-manifold modeled on the geometry \((G,G)\), where \(G\) is a simply-connected unimodular Lie group, and let \(\nu(g) = (\nu_1(g), \nu_2(g), \nu_3(g))\) be the vector consisting of eigenvalues of the associated Ricci tensor \(\text{Ric}\).

1. If \(P_3(\nu(g))\) is zero (i.e., \(\text{Ric}\) is degenerate), then \(P_2(\nu(g))\) is zero.
2. \(P_2(\nu(g))\) is non-negative if and only if (up to reordering of the Ricci eigenvalues) one of the following holds:
   a. \(G = \text{SL}_2(\mathbb{R})\) and \(\text{Ric}\) has signature
      i. \((0,0,-), \) or
      ii. \((+, -, -), \) where \(\nu_1(g) > 0 > \nu_2(g) \geq \nu_3(g)\)
   b. \(G = S^3\) and \(\text{Ric}\) has signature \((+, +, +)\) or \((+, 0, 0)\);
   c. \(G = \text{Sol}\) and \(\text{Ric}\) has signature \((0, 0, -)\); or
   d. \(G = \mathbb{R}^3\) and \(\text{Ric}\) has signature \((0, 0, 0)\).

Consequently, \(P_2(\nu(g))\) is positive if and only if either

\[ \text{(1) } G = S^3 \text{ and } \text{Ric has signature } (+, +, +), \text{ or } \text{(2) } G = \text{SL}_2(\mathbb{R}) \text{ and } \text{Ric has signature } (+, -, -) \text{ and } \nu_1(g) < -\frac{\nu_2(g)\nu_3(g)}{\nu_2(g) + \nu_3(g)}. \]

Proof. — The first statement follows immediately from Lemma 3.2. As for the second statement, it follows directly from Lemmas 2.9 and 2.10. □

We now recall the following observation of Milnor.

Lemma 3.4 ([22], Lemma 4.1). — Let \(G\) be a connected three-dimensional Lie group with Lie algebra \(\mathfrak{g}\) and equipped with a left-invariant metric \(g\). Fix an orientation \(\Omega\) on \(\mathfrak{g}\) and let \(\times : \mathfrak{g} \times \mathfrak{g} \to \mathfrak{g}\) be the cross-product determined by the inner product \(\langle \cdot, \cdot \rangle = g(e(\cdot, \cdot)). \) Then, the Lie bracket on \(\mathfrak{g}\) and the cross-product are related via the following formula

\[
[u, v] = L(u \times v),
\]

where \(L : \mathfrak{g} \to \mathfrak{g}\) is a uniquely defined linear mapping. Furthermore, \(G\) is unimodular if and only if \(L\) is self-adjoint with respect to \(\langle \cdot, \cdot \rangle\).

As in Lemma 2.5, in the case where \(G\) is unimodular, let \(\{e_1, e_2, e_3\}\) be an orthonormal basis of \(L\)-eigenvectors with corresponding eigenvalues \(\lambda_1, \lambda_2\) and \(\lambda_3\). Then, \(\{e_1, e_2, e_3\}\) is also an orthonormal basis of \(\text{Ric}(g)\)-eigenvectors with corresponding eigenvalues \(\nu_1 = 2\mu_2 \mu_3, \nu_2 = 2\mu_1 \mu_3\) and
\( \nu_3 = 2\mu_1\mu_2, \) where
\[
(3.2) \quad \begin{pmatrix} \mu_1 \\ \mu_2 \\ \mu_3 \end{pmatrix} = \frac{1}{2} \begin{pmatrix} -1 & 1 & 1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \end{pmatrix} \begin{pmatrix} \lambda_1 \\ \lambda_2 \\ \lambda_3 \end{pmatrix}.
\]

Conversely, let \( \mathcal{V} \) be the collection of \( \nu \in \mathbb{R}^3 \) for which – up to ordering – the signs of the components of \( \nu \) are given by \((+, +, +), (+, -, -), (+, 0, 0), (0, 0, -) \) and \((0, 0, 0)\).

Then, for any \( \nu = (\nu_1, \nu_2, \nu_3) \in \mathcal{V} \) there is a unimodular Lie group \( G \) and a left-invariant metric \( g \in \mathcal{R}_G(G) \) such that the eigenvalues of the associated Ricci tensor \( \text{Ric}(g) \) are given by \( \nu_1, \nu_2 \) and \( \nu_3 \).

**Remark 3.5.** — The reader is encouraged to compare the statement of Lemma 3.4 with Lemma 2.5.

**Definition 3.6.** — Let \((\mathfrak{g}, \langle \cdot, \cdot \rangle)\) be an oriented metric Lie algebra with corresponding cross-product \( \times \). The unique linear transformation \( L : \mathfrak{g} \to \mathfrak{g} \) such that \( [u, v] = L(u \times v) \) is called the Milnor map. In the case where \( \mathfrak{g} \) is unimodular, the eigenvalues of \( L \) are referred to as the Milnor eigenvalues.

From Lemma 3.4 we deduce the following.

**Lemma 3.7.** — Let \( \mathfrak{g} \) be the Lie algebra of a simply-connected three-dimensional unimodular Lie group \( G \). For \( j = 1, 2 \), let \( \times_j \) be the cross-product on \( \mathfrak{g} \) determined by the inner product \( \langle \cdot, \cdot \rangle_j \) and orientation \( \Omega_j \), and let \( L_j : \mathfrak{g} \to \mathfrak{g} \) be the Milnor map corresponding to \( \times_j \). Additionally, for \( j = 1, 2 \), let \( \mathcal{B}_j = \{ e_{j1}, e_{j2}, e_{j3} \} \) be a positively oriented \( \langle \cdot, \cdot \rangle_j \)-orthonormal basis consisting of \( L_j \)-eigenvectors with \( L_j(e_{jk}) = \lambda_{jk} e_{jk} \) for \( k = 1, 2, 3 \). If \( (\lambda_{11}, \lambda_{12}, \lambda_{13}) = \pm(\lambda_{21}, \lambda_{22}, \lambda_{23}) \), then there is a Lie group automorphism \( \Phi \in \text{Aut}(G) \) such that \( \Phi : (G, g_1) \to (G, g_2) \) is an isometry, where \( g_j \) is the left-invariant metric induced by \( \langle \cdot, \cdot \rangle_j \), for each \( j = 1, 2 \).

**Proof.** — Depending on whether \( (\lambda_{11}, \lambda_{12}, \lambda_{13}) = \pm(\lambda_{21}, \lambda_{22}, \lambda_{23}) \), let \( \phi^\pm : \mathfrak{g} \to \mathfrak{g} \) be the linear map determined by \( e_{1k} \mapsto \pm e_{2k} \), for \( k = 1, 2, 3 \). Since, we have
\[
\begin{align*}
[e_{j1}, e_{j2}] &= L_j(e_{j1} \times_j e_{j2}) = L_j(e_{j3}) = \lambda_{j3} e_{j3} \\
[e_{j2}, e_{j3}] &= L_j(e_{j2} \times_j e_{j3}) = L_j(e_{j1}) = \lambda_{j1} e_{j1} \\
[e_{j3}, e_{j1}] &= L_j(e_{j3} \times_j e_{j1}) = L_j(e_{j2}) = \lambda_{j2} e_{j2},
\end{align*}
\]
for \( j = 1, 2 \), we may conclude that \( \phi^\pm \) is a Lie algebra isomorphism. One can check that the corresponding automorphism \( \Phi^\pm \in \text{Aut}(G) \) is an isometry between \((G, g_1)\) and \((G, g_2)\). \( \square \)

(4) By Lemma 2.9, if \( \nu \) is a triple consisting of Ricci-eigenvalues of a left-invariant metric on a three-dimensional unimodular Lie group, then \( \nu \) is in \( \mathcal{V} \).
We now establish that, on a three-dimensional simply-connected uni-
modular Lie group, isometry classes of left-invariant metrics possessing
non-degenerate Ricci tensor can be mutually distinguished by the eigenval-
ues of their respective Ricci tensors.

**Proposition 3.8.** — Let $G$ be a simply-connected non-abelian unimod-
ular Lie group of dimension three. And, for $j = 1, 2$, let $g_j$ be a left-invariant
metric on $G$ with non-degenerate Ricci tensor $\text{Ric}_j$. Then, $\text{Ric}_1$ and $\text{Ric}_2$
have the same eigenvalues if and only if $(G, g_1)$ and $(G, g_2)$ are isometric
(via a Lie group automorphism). In the case where $G$ is $E(2)$ we may re-
move the non-degeneracy condition; however, the flat left-invariant metrics
on $G$ will not be isometric via a Lie group automorphism.

**Remark 3.9.** — The authors wish to thank Dorothee Schueth for sug-
gestions on how this might be proven.

**Proof of Proposition 3.8.** — Let $g$ be a left-invariant metric on the group
$G$ determined by the inner product $\langle \cdot, \cdot \rangle$ on $g$. Fix an orientation on
$g$ and let $\times$ be the cross product determined by the inner product $\langle \cdot,\cdot \rangle = g_e$. Let
$L : (g, \langle \cdot, \cdot \rangle) \to (g, \langle \cdot, \cdot \rangle)$ be the self-adjoint map described in Lemma 3.4 and
let $\{e_1, e_2, e_3\}$ be an orthonormal basis consisting of $L$-eigenvectors with
corresponding eigenvalues $\lambda_1$, $\lambda_2$, and $\lambda_3$. Then, for $k = 1, 2, 3$, $\text{Ric}(e_k) = \nu_k e_k$, where

\begin{equation}
\nu_1 = 2\mu_2\mu_3, \quad \nu_2 = 2\mu_1\mu_3, \quad \text{and} \quad \nu_3 = 2\mu_1\mu_2,
\end{equation}

and

\begin{equation}
\begin{pmatrix}
\lambda_1 \\
\lambda_2 \\
\lambda_3
\end{pmatrix} =
\begin{pmatrix}
0 & 1 & 1 \\
1 & 0 & 1 \\
1 & 1 & 0
\end{pmatrix}
\begin{pmatrix}
\mu_1 \\
\mu_2 \\
\mu_3
\end{pmatrix}.
\end{equation}

We will now see that (up to sign) the vector $\lambda = (\lambda_1, \lambda_2, \lambda_3)$ can be recov-
ered from the vector $\nu = (\nu_1, \nu_2, \nu_3)$. The first statement of the corollary
will then follow from a direct application of Lemma 3.7.

Indeed, by Lemma 2.9, the Ricci tensor of a unimodular Lie group is
non-degenerate if and only if its signature is $(+, +, +)$ and $(+, -, -)$. The
signature $(+, +, +)$ can only occur for the group $S^3$ in which case the entries
of the vector $\mu = (\mu_1, \mu_2, \mu_3)$ are all positive or all negative. In any event,
for any cyclic permutation $\sigma$ we have:

$$
\mu^2_{\sigma(1)} = \frac{\nu_{\sigma(2)}\nu_{\sigma(3)}}{2\nu_{\sigma(1)}},
$$

and we conclude that (up to sign) we may recover the vector $\mu$ from the
Ricci eigenvalues. And, in turn, we may recover the vector $\lambda$ from $\mu$ (up
to sign). On the other hand, consulting Lemma 2.9 again, we see that every three-dimensional non-abelian unimodular Lie group supports a left-invariant metric for which the Ricci tensor has signature $(+, -, -)$. In this case the signs of the entries of the vector $\mu = (\mu_1, \mu_2, \mu_3)$ must be $(+, - , -)$ or $(-, +, +)$. Once again, we see that for any cyclic permutation $\sigma$ we have

$$\mu_{\sigma(1)}^2 = \frac{\nu_{\sigma(2)}\mu_{\sigma(3)}}{2\nu_{\sigma(1)}},$$

and we conclude that (up to sign) we may recover the vector $\mu$ from the Ricci eigenvalues. And, in turn, we may recover the vector $\lambda$ from $\mu$ (up to sign). This establishes the first statement.

In the case where $G$ is $\widetilde{E}(2)$, the left-invariant metrics with degenerate Ricci tensor are all flat – which in dimension three is equivalent to being Ricci-flat – and are, therefore, isometric. This establishes the last statement. $\square$

**Corollary 3.10.** — Among compact locally homogeneous three-manifolds modeled on a metrically maximal geometry of the form $(G, G)$, where $G$ is a simply-connected, non-abelian unimodular Lie group (i.e., $(G, G)$ is chosen from among the metrically maximal geometries (MM1), (MM2), (MM6), (MM7) and (MM8)), the first four heat invariants of a three-manifold $(M, g)$ with non-degenerate Ricci curvature determine the isometry class of its universal cover up to two possibilities.

**Proof.** — Let $(M, g)$ be a compact locally homogeneous three-manifold with non-degenerate Ricci tensor modeled on $(G, G)$, chosen from among the metrically maximal geometries (MM1), (MM2), (MM6), (MM7) and (MM8). As, the Ricci tensor is assumed to be non-degenerate we see that $P_3(\nu(g)) \neq 0$. Therefore, as in Theorem 2.22, we may set

$$C(M, g) = \frac{6P_1^2(\nu(g))P_2^2(\nu(g)) - 24P_2^3(\nu(g))}{30P_3(\nu(g))}.$$

Now, suppose $(N, h)$ is another compact locally homogeneous three-manifold modeled on one of the metrically maximal geometries (MM1), (MM2), (MM6), (MM7) and (MM8) and that $a_j(N, h) = a_j(M, g)$, for $j = 0, \ldots, 3$. Then, by Theorem 2.18 and 2.22, $P_1(\nu(h)) = P_1(\nu(g))$, $P_2(\nu(h)) = P_2(\nu(g))$, and either $P_3(\nu(h)) = P_3(\nu(g))$ or $P_3(\nu(h)) = C(M, g)$. Hence, up to rearrangement, $\nu(h) = (\nu_1(h), \nu_2(h), \nu_3(h))$ takes on at most two values. The result now follows from Proposition 3.8. $\square$
3.1. On the audibility of locally symmetric spaces of rank two

We will establish that among locally homogeneous three-manifolds, compact Riemannian manifolds modeled on the $S^2 \times \mathbb{R}$-geometry (respectively, the $\mathbb{H}^2 \times \mathbb{R}$-geometry) are determined up to local isometry by their spectra. Later, in Section 4, we will prove the spaces modeled on the $S^2 \times \mathbb{R}$-geometry are actually uniquely determined by their spectra among locally homogeneous three-manifolds.

**Theorem 3.11.** — Let $(M, g)$ and $(M', g')$ be two locally homogeneous three-manifolds with the property that $a_j(M, g) = a_j(M', g')$, for $j = 0, 1, 2, 3$. And, fix a positive real number $k$. Then, $(M, g)$ is locally isometric to $S^2_k \times \mathbb{E}$ (respectively, $\mathbb{H}^2_{-k} \times \mathbb{E}$) if and only if $(M', g')$ is locally isometric to $S^2_k \times \mathbb{E}$ (respectively, $\mathbb{H}^2_{-k} \times \mathbb{E}$).

**Proof.** — Throughout we will let $M(k)$ denote the simply-connected surface of constant sectional curvature $k$. Now, fix $k > 0$ and assume that $(M, g)$ is locally isometric to $M(k) \times \mathbb{E}$. Then, the principal curvatures are $K_{12} = k$ and $K_{13} = K_{23} = 0$, or equivalently the principal Ricci curvatures are $\nu_1 = \nu_2 = k$ and $\nu_3 = 0$. By Corollary 2.21, the assumption that the first four heat invariants of $(M, g)$ and $(M', g')$ are identical is equivalent to: $a_0(M, g) = a_0(M', g')$, $P_1(\nu(g)) = P_1(\nu(g'))$, $P_2(\nu(g)) = P_2(\nu(g'))$ and $a_3(M, g) = a_3(M', g')$. So, we obtain

\[
\begin{align*}
a_0(M, g) &= a_0(M', g') \\
P_1(\nu(g)) &= 2k = P_1(\nu(g')) \\
P_2(\nu(g)) &= k^2 = P_2(\nu(g')) \\
a_3(M, g) &= a_3(M', g') \\
P_3(\nu(g)) &= 0.
\end{align*}
\]

Let’s first assume that $(M', g')$ is a locally symmetric three-manifold. Then, since three-manifolds of constant sectional curvature are uniquely determined up to local isometry by their first three heat invariants [4, Theorem 7.1], we see that $(M', g')$ is locally isometric to $M(k) \times \mathbb{E}$ for some $k' \neq 0$. Then, $2k' = P_1(\nu(g')) = 2k$ and, therefore, $(M, g)$ and $(M', g')$ are locally isometric. What remains is to show that $(M', g')$ cannot be covered by a unimodular Lie group equipped with a left-invariant metric of (non-constant sectional curvature).

Suppose, $(M', g')$ is not locally symmetric. Then, it must be locally isometric to a unimodular Lie group equipped with a left-invariant metric (of non-constant curvature). We first observe that in this case $P_3(\nu(g')) \neq 0$. 

Indeed, suppose $P_3(\nu(g')) = 0$. Then, by Lemma 3.3, $P_2(\nu(g')) = 0$, which contradicts our assumption on the heat invariants. Therefore, $P_3(\nu(g')) > 0$, since $P_3(\nu)$ is non-negative for any three-dimensional unimodular Lie group (Lemma 3.2) and we conclude that $\text{Ric}(g')$ is non-degenerate.

Since $(M', g')$ is locally isometric to a unimodular Lie group and $P_3(\nu(g')) > 0$, we see by Theorem 2.18 that
\[
a_3(M', g') = \frac{a_0(M', g')}{7!} (40k^3 - 30P_3(\nu(g'))).
\]
On the other hand,
\[
a_3(M', g') = \frac{a_0(M, g)}{7!} 64k^3.
\]
Therefore, we find $P_3(\nu(g')) = -\frac{24}{30}k^3$ (and conclude that $k < 0$). Now, the Ricci eigenvalues $\nu_1(g'), \nu(g')$ and $\nu_3(g')$ are real roots of
\[
0 = x^3 + P_1(\nu(g'))x^2 + P_2(\nu(g'))x + P_3(\nu(g'))
= x^3 + 2kx^2 + k^2x - \frac{24}{30}k^3.
\]
However, since the discriminant of this polynomial is negative, we conclude that it cannot have three real roots. Therefore, $(M', g')$ cannot be covered by a unimodular Lie group equipped with a left-invariant metric. □

**Corollary 3.12.** — Among compact locally homogeneous three-manifolds, locally symmetric spaces are determined up to local isometry by their first four heat invariants.

Proof. — This follows immediately from Theorem 3.11 and [4, Theorem 7.1]. □

**3.2. On the audibility of three-dimensional nilmanifolds**

There are countably infinite non-diffeomorphic three-dimensional manifolds admitting geometric structures modeled on (Nil, Nil), the Nil-geometry [16, Corollary 2.5]. We will establish that among locally homogeneous three-manifolds, the property of being modeled on (Nil, Nil) is encoded in the spectrum. In fact, among locally homogeneous spaces, nilmanifolds are determined up to local isometry by their spectra. Coupling this result with a result of Gordon and Wilson, we will conclude that a nilmanifold is actually uniquely determined by its spectrum among all compact locally homogeneous three-manifolds.
Theorem 3.13. — Let \((M, g)\) and \((M', g')\) be two locally homogeneous three-manifolds with the property that \(a_j(M, g) = a_j(M', g')\), for \(j = 0, 1, 2, 3\). If \((M, g)\) is modeled on \((\text{Nil}, \text{Nil})\), then \((M', g')\) is locally isometric to \((M, g)\).

Proof. — Since \((M, g)\) is modeled on \((\text{Nil}, \text{Nil})\), its Ricci tensor has signature \((+, -, -)\) by Lemma 2.9; in particular, it is non-degenerate. And, by Lemma 2.10, without loss of generality we may assume the eigenvalues of its Ricci tensor are given by \(\nu_1 = |\nu_2| = |\nu_3| = c > 0\). This coupled with our assumption on the heat invariants implies (via Corollary 2.21)

\[
\begin{align*}
b_1(M, g) &= P_1(\nu) = -c = P_1(\nu') \equiv b_1(M', g') \\
b_2(M, g) &= P_2(\nu) = -c^2 = P_2(\nu') = b_2(M', g') \\
P_3(\nu) &= c^3
\end{align*}
\]

Now, since locally symmetric spaces are determined up to local isometry by their first four heat invariants (see Corollary 3.12), we see that \((M', g')\) must be modeled on a non-abelian unimodular Lie group equipped with a left-invariant metric (of non-constant curvature). Furthermore, since \(P_2(\nu') = -c^2\) is non-zero, Lemma 3.3 implies \(P_3(\nu')\) must be non-zero (and, hence, \(\text{Ric}(g')\) is non-degenerate). Therefore, by Theorem 2.22, we see that

\[
P_3(\nu') = P_3(\nu)
\]

or

\[
P_3(\nu') = \frac{6P_1^2(\nu)P_2^2(\nu) - 24P_3^3(\nu)}{30P_3(\nu)} = c^3 = P_3(\nu).
\]

In both cases we have \(P_j(\nu') = P_j(\nu)\) for \(j = 1, 2, 3\). Therefore, by Lemma 3.1, \(\text{Ric}\) and \(\text{Ric}'\) have the same eigenvalues and consequently both are of signature \((+, -, -)\). It follows from Lemma 2.10 that \((M', g')\) is also modeled on \((\text{Nil}, \text{Nil})\) and by Proposition 3.8 we conclude that \((M, g)\) and \((M', g')\) are locally isometric.

We now establish that three-dimensional compact nilmanifolds are uniquely characterized by their spectra within the universe of locally homogeneous three-manifolds.

Proof of Corollary 1.4. — Gordon and Wilson have previously shown that in dimension three nilmanifolds can be mutually distinguished via their spectra [16]. The result now follows by applying Theorem 3.13.
3.3. On the audibility of locally homogeneous platycosms

We recall that \((E(2), E(2))\), which we refer to as the \(E(2)\)-geometry, is a sub-geometry of \((\mathbb{R}^3, \text{Isom}(\mathbb{E}^3))\). As we noted in the introduction, there are ten compact manifolds – sometimes referred to as “platycosms” – that admit \(E(2)\)-geometries [10]. Five of these platycosms are of the form \(\Gamma \backslash E(2)\) for some co-compact discrete subgroup of \(E(2)\) [27] and, as a consequence, admit non-flat structures. In particular, the three-torus can be realized in this manner. We show that, within the class of locally homogeneous three-manifolds, such a space is distinguished up to local isometry by its spectrum.

**Theorem 3.14.** — Let \((M, g)\) and \((M', g')\) be two locally homogeneous three-manifolds with Ricci tensors \(\text{Ric}\) and \(\text{Ric}'\), respectively, and such that \(a_j(M, g) = a_j(M', g')\), for \(j = 0, 1, 2, 3\). If \((M, g)\) is modeled on the \(E(2)\)-geometry, then \((M', g')\) is locally isometric to \((M, g)\).

**Proof.** — Since, as has been noted previously, closed three-manifolds of constant sectional curvature are determined up to local isometry by their first three heat invariants [4, Theorem 7.1], we may assume that \((M, g)\) is a non-flat space modeled on the \(E(2)\)-geometry. Then, the signature of its Ricci tensor is \((+, -, -)\); in particular, it is non-degenerate. And, Lemma 2.10 tells us the Ricci eigenvalues are given by \(\nu_1 = |\nu_3| \equiv c > |\nu_2| \equiv d > 0\). Taking into account the assumption on the heat invariants, we then obtain

\[
\begin{align*}
P_1(\nu) &= -d = P_1(\nu') \\
P_2(\nu) &= -c^2 = P_2(\nu') \\
P_3(\nu) &= c^2d > 0.
\end{align*}
\]

Now, by Corollary 3.12, we know \((M', g')\) must be modeled on a unimodular Lie group equipped with a left-invariant metric (of non-constant curvature). Since \(P_2(\nu')\) is non-zero, Lemma 3.3 informs us that \(P_3(\nu')\) is non-zero (and, therefore, \(\text{Ric}(g')\) is non-degenerate). Applying Theorem 2.22, we find \(P_3(\nu') = P_3(\nu)\) or \(P_3(\nu') = \frac{c^4d^2 - 4c^6}{5c^2d} < 0\).

The latter option cannot occur, because the product of the Ricci eigenvalues of a left-invariant metric on a three-dimensional unimodular Lie group must be non-negative (see Lemma 3.2). So, we have \(P_j(\nu) = P_j(\nu')\) for \(j = 1, 2, 3\). Therefore, \(\text{Ric}\) and \(\text{Ric}'\) have the same eigenvalues and, therefore, signature
By Lemma 2.10, we conclude that \((M', g')\) is a non-flat space modeled on the \(E(2)\)-geometry, and by Proposition 3.8 we see that \((M, g)\) and \((M', g')\) are locally isometric.

Theorems 3.11, 3.13 and 3.14 establish statement (1) of Theorem 1.1 from which we may deduce the following.

**Corollary 3.15.** — Let \((M, g)\) be a compact three-manifold whose universal Riemannian cover is a symmetric space, \(\text{Nil}\) equipped with a left-invariant metric, or \(E(2)\) equipped with a left-invariant metric. Then, among compact locally homogeneous three-manifolds, \((M, g)\) is determined up to local isometry by its first four heat invariants.

**Proof.** — Follows directly from Corollary 3.12 and Theorems 3.11, 3.13 and 3.14.

### 3.4. On the audibility of locally homogeneous elliptic three-manifolds

An elliptic \(n\)-manifold is a manifold \(\Gamma \backslash S^n\), where \(\Gamma \leq \text{Diff}(S^n)\) acts freely and properly discontinuously. Up to diffeomorphism, an elliptic three-manifold is of the form \(\Gamma \backslash S^3\), where \(\Gamma \leq \text{SO}(4)\) belongs to one of six infinite families of finite groups, and the locally homogeneous elliptic three-manifolds are precisely the Riemannian manifolds modeled on the metrically maximal geometry \((S^3, S^3)\). Our objective is to establish that the property of being a locally homogeneous elliptic three-manifold is audible among compact locally homogeneous three-manifolds and the signature of the Ricci tensor of such manifolds is spectrally determined. Furthermore, for certain left-invariant metrics \(g_0\) on \(S^3\) (e.g., constant curvature metrics), we find that for \(g\) sufficiently close to \(g_0\), the universal Riemannian cover \((S^3, g)\) is encoded in the spectra of its compact quotients.

**Theorem 3.16.**

1. Let \((M, g)\) and \((M', g')\) be two locally homogeneous three-manifolds with Ricci tensors \(\text{Ric} \text{ and } \text{Ric}'\), respectively, and such that \(a_j(M, g) = a_j(M', g')\), for \(j = 0, 1, 2, 3\). And, suppose further that \((M, g)\) is modeled on the \(S^3\)-geometry. Then, \((M', g')\) is also modeled on the \(S^3\)-geometry, and \(\text{Ric} \text{ and } \text{Ric}'\) have the same signature. In fact, if either (a) \(\text{Ric}\) has signature \((+, 0, 0)\) or (b) \((M, g)\) has negative scalar curvature and \(\text{Ric}\) has signature \((+, -, -)\), then \(\text{Ric} \text{ and } \text{Ric}'\) have...
Ric’ have the same eigenvalues. In particular, when $(M, g)$ has negative scalar curvature and Ric has signature $(+, -, -)$, then $(M, g)$ and $(M', g')$ are locally isometric.

(2) Let $g_0$ be a left-invariant metric on $S^3$ with non-degenerate Ricci tensor and such that $C(S^3, g_0)$ (see Theorem 2.22 for definition) is negative. Then, within the space of left-invariant metrics on $S^3$, there is a neighborhood $U$ of $g_0$ such that, among compact locally homogeneous three-manifolds, a space with universal Riemannian cover $(S^3, g)$, for some $g \in U$, is determined up to local isometry by its first four heat invariants.

We have the following immediate corollary.

**Corollary 3.17.**

1. Let $(M, g)$ and $(M', g')$ be two locally homogeneous three-manifolds modeled on the $S^3$-geometry and for which $a_j(M, g) = a_j(M', g')$, for $j = 0, 1, 2, 3$. Then, $(M, g)$ has non-degenerate Ricci tensor if and only if $(M', g')$ has non-degenerate Ricci tensor.

2. Within the space of left-invariant metrics on $S^3$, there is a neighborhood $U$ of the round metric such that, among locally homogeneous three-manifolds, a quotient of an $S^3$-geometry contained inside $U$ is determined up to local isometry by its first four heat invariants.

As preparation for the proof of Theorem 3.16 we note that Lemma 2.10 implies that, up to ordering, the set of all possible eigenvalues of the Ricci tensor of a left-invariant metric on $S^3$ with signature $(+, -, -)$ and negative scalar curvature is given by

$$S = \{ (\alpha, \beta, \gamma) : \alpha > 0 > \beta \geq \gamma, \alpha > |\gamma| \text{ and } \alpha + \beta + \gamma < 0 \}.$$

We then have the following fact that will be useful in our proof.

**Lemma 3.18.** — The homogeneous symmetric polynomial

$$f(\alpha, \beta, \gamma) := P_2^2 - \frac{P_2^2(P_1^2 - 4P_2)}{5}$$

is nonpositive on $S$, where $P_j \equiv P_j(\alpha, \beta, \gamma)$, for $j = 1, 2, 3$.

**Proof.** — As the polynomial $f$ is symmetric and homogeneous, it suffices to show that $f$ is nonpositive on the set

$$S_1 = \{ (1, \beta, \gamma) : 0 \geq \beta \geq \gamma \geq -1 \text{ and } \beta + \gamma < -1 \}.$$
To verify the nonpositivity of \( f \) on the domain \( S_1 \), we do a change of variables:
\[
\begin{align*}
    x &:= \beta + \gamma \\
y &:= \beta \gamma.
\end{align*}
\]
and show the nonpositivity of
\[
f(x, y) = y^2 - \frac{1}{5}(x + y)((1 + x)^2 - 4(x + y))
\]
on \( S_2 = \{(x, y) \mid -2 \leq x \leq -1, 0 \leq y \leq (1/4)x^2\} \).

First, note that
\[
\frac{\partial f}{\partial y} = 2y - \frac{2}{5}(x + y)(1 + x^2 - 2x - 4y) + \frac{4}{5}(x + y)^2 > 0
\]
on \( S_2 \). Therefore, the function \( f \) has no critical point on the interior of \( S_2 \).

Now, we check the values of the function along the upper boundary curve \( r(t) = (t, t^2/4), t \in [-2, -1] \).

Simple calculus shows that the function \( g(t) = f(t, t^2/4) \) is indeed non-positive on the interval. The partial derivative condition (3.7) then implies that \( f \) is nonpositive on \( S_2 \), proving the Lemma.

Proof of Theorem 3.16.

(1). — We begin by collecting some facts about the manifolds \((M, g)\) and \((M', g')\). By applying Corollary 3.15 we may assume that \((M, g)\) is a space of non-constant sectional curvature modeled on the \(S^3\)-geometry. Then, Lemma 2.9 tells us that \(\text{Ric} \) has signature \((+, +, +), (+, 0, 0)\) or \((+, -, -)\). Applying Corollary 3.15 once again, we see that \((M', g')\) is a space of non-constant sectional curvature modeled on \((G, G)\), where \(G\) is one of the unimodular Lie groups \(S^3\), \(\text{Sol}\) or \(\text{SL}_2(\mathbb{R})\). We also observe that combining Theorem 2.18 with our assumption on the heat invariants implies \(P_1(\nu(g)) = P_1(\nu(g'))\) and \(P_2(\nu(g)) = P_2(\nu(g'))\).

Now, lets assume \(\text{Ric} \) has signature \((+, +, +)\). Then, \(P_1(\nu(g)), P_2(\nu(g))\) and \(P_3(\nu(g))\) are all positive. It follows that \(\text{Scal}(g') = P_1(\nu(g')) = P_1(\nu(g))\) is positive and, by Lemma 2.9, we conclude \((M', g')\) must be (a space of non-constant sectional curvature) modeled on the \(S^3\)-geometry. If \(\text{Ric}'\) were to have signature \((+, 0, 0)\), then we would have \(P_2(\nu(g)) = 0\), a contradiction. Similarly, if \(\text{Ric}'\) were to have signature \((+, -, -)\), then Lemma 2.10(1) implies \(P_2(\nu(g)) = P_2(\nu(g'))\) is negative, which is also a contradiction. Therefore, we conclude that \(\text{Ric}'\) must also have signature \((+, +, +)\). Then, by Theorem 2.22, we find \(P_3(\nu')\) takes on at most two
values. Therefore, by Lemma 3.1 and Proposition 3.8, there are at most two isometry classes for the universal Riemannian cover of \((M', g')\).

Next, suppose that \((M, g)\) is such that Ric has signature \((+, 0, 0)\). Then, \(P_1(\nu(g))\) is positive, while \(P_2(\nu(g))\) and \(P_3(\nu(g))\) are both zero. Then, once again, \(\text{Scal}(g') = P_1(\nu(g')) = P_1(\nu(g))\) is positive and, appealing to Lemma 2.9, we conclude that \((M', g')\) must be modeled on one of the unimodular Lie groups \(\text{Sol}, \text{SL}_2(\mathbb{R})\) or \(S^3\) equipped with a left-invariant metric (of non-constant curvature), Lemma 2.9 implies Ric' also has signature \((+, -, -)\).

To see that \((M', g')\) is modeled on an \(S^3\)-geometry, we first observe that if \(P_1(\nu(g')) = P_1(\nu(g))\) is non-negative (i.e., both spaces are of non-negative scalar curvature), then Lemma 2.9 implies \((M', g')\) must be modeled on an \(S^3\)-geometry (of non-constant sectional curvature).

Now, suppose \(P_1(\nu(g')) = P_1(\nu(g))\) is negative (i.e., both spaces are of negative scalar curvature) and notice that, since \(P_3(\nu(g))\) and \(P_3(\nu(g'))\) are both non-zero, Theorem 2.22 implies \(P_3(\nu(g)) = P_3(\nu(\nu'))\) or

\[
P_3(\nu(\nu')) = \frac{P_2^2(\nu(g)) P_2(\nu(g)) - 4 P_2^3(\nu(g))}{5 P_3(\nu(g))}.
\]

In the first case, we obtain \(P_j(\nu(g)) = P_j(\nu(g'))\) for \(j = 1, 2, 3\), and conclude by Lemma 3.1 that Ric and Ric' have the same eigenvalues and, by Lemma 2.10, both are modeled on \(S^3\). In the second case, since \(\nu(g) = (\nu_1(g), \nu_2(g), \nu_3(g))\) is an element of the set \(\mathcal{S}\), Lemma 3.18 informs us that

\[
P_3(\nu(g')) \geq P_3(\nu(g)).
\]

Then, recalling that \(P_j(\nu(g)) = P_j(\nu(g'))\) for \(j = 1, 2\) and comparing the equations

\[
0 = x^3 + P_1(\nu') x^2 + P_2(\nu') x + P_3(\nu') = (x + \nu'_1)(x + \nu'_2)(x + \nu'_3)
\]
and

\[ 0 = x^3 + P_1(\nu)x^2 + P_2(\nu)x + P_3(\nu) = (x + \nu_1)(x + \nu_2)(x + \nu_3), \]

we determine that \( \nu(g') = (\nu_1(g'), \nu_2(g'), \nu_3(g')) \) is also in \( S \). By Lemma 2.10 and the definition of \( S \), we conclude that \((M', g')\) is modeled on an \( S^3 \)-geometry for which \( \text{Ric}' \) also has signature \((+, -, -)\), but with possibly different eigenvalues from those of \( \text{Ric} \). However, now that \( \nu(g') \) is in \( S \) we may reverse the roles of \((M, g)\) and \((M', g')\) to obtain (via Lemma 3.18 and Theorem 2.22) \( P_3(\nu(g)) \geq P_3(\nu(g')) \). Hence, \( P_3(\nu(g)) = P_3(\nu(g')) \) for \( j = 1, 2, 3 \) and, by Lemma 3.1, we conclude that \( \text{Ric} \) and \( \text{Ric}' \) have the same eigenvalues, all of which are non-zero. Therefore, applying Proposition 3.8 \((M', g')\) and \((M, g)\) are locally isometric.

(2). Throughout, we let \( \mathcal{R}_{\text{left}}(S^3) \) denote the space of left-invariant metrics on \( S^3 \) and recall that \( C(M, g) \equiv \frac{6P_2(\nu(g))P_3(\nu(g)) - 24P_4(\nu(g))}{30P_3(\nu(g))} \), where \( \nu(g) \) is the vector of eigenvalues of the Ricci tensor associated to \((M, g)\). Now, let \( g \in \mathcal{R}_{\text{left}}(S^3) \) have non-degenerate Ricci tensor (i.e., \( P_3(\nu(g)) > 0 \)) and be such that \( C(S^3, g) \) is negative. Then, there is a neighborhood \( U \) of \( g \) in \( \mathcal{R}_{\text{left}}(S^3) \) such that \( C(S^3, h) \) is negative and \( P_3(\nu(h)) \) is positive for each \( h \in U \). Suppose \((M, h)\) is modeled on \((S^3, \tilde{h})\) for some \( \tilde{h} \in U \) and let \((M', h')\) be a compact locally homogeneous three-manifold such that \( a_j(M', h') = a_j(M, h) \), for \( j = 0, 1, 2, 3 \). Then, by part (1) of the theorem, we know \((M', h')\) is locally isometric to an \( S^3 \)-geometry and has non-degenerate Ricci tensor. Also, by Theorem 2.18, \( P_1(\nu(h')) = P_1(\nu(h)) \) and \( P_2(\nu(h')) = P_2(\nu(h)) \). Since both \((M, h)\) and \((M', h')\) have non-degenerate Ricci tensor, Theorem 2.22 implies \( P_3(\nu(h')) = P_3(\nu(h)) \) or \( P_3(\nu(h')) = C(M, h) < 0 \). The latter option contradicts Lemma 3.2, so we conclude \( P_3(\nu(h')) = P_3(\nu(h)) \) for \( j = 1, 2, 3 \). Applying Lemma 3.1 and Proposition 3.8, we conclude \((M, h)\) and \((M', h')\) are locally isometric. \( \square \)

3.5. On the audibility of manifolds modeled on \((\text{Sol}, \text{Sol})\) and \((\widetilde{\text{SL}_2(\mathbb{R})}, \widetilde{\text{SL}_2(\mathbb{R})})\)

Theorems 3.11, 3.13, 3.14 and 3.16 establish the first and second statement of Theorem 1.1 from which we may deduce the following.

**Corollary 3.19.** Let \((M, g)\) and \((M', g')\) be two locally homogeneous three-manifolds with the property that \( a_j(M, g) = a_j(M', g') \), for \( j = 0, 1, 2, 3 \). Then, \((M, g)\) is modeled on \((\text{Sol}, \text{Sol})\) or \((\widetilde{\text{SL}_2(\mathbb{R})}, \widetilde{\text{SL}_2(\mathbb{R})})\) if and only if \((M', g')\) is modeled on \((\text{Sol}, \text{Sol})\) or \((\widetilde{\text{SL}_2(\mathbb{R})}, \widetilde{\text{SL}_2(\mathbb{R})})\)
Theorem 2.18, the hypothesis on the heat invariants implies (possibly rearranging the eigenvalues). Furthermore, if the eigenvalues); that is, \( P \) \( g \) is such that \( R_{i}^{2}(g) < 0 \) and is such that \( P_{2}(g) \) \( g \) is modeled on the \( \mathbb{SL}_{2}(\mathbb{R}) \)-geometry (resp., Sol-geometry). Then, among locally homogeneous Riemannian three-manifolds, up to isometry, there are exactly two possible universal Riemannian covers of a manifold possessing the same first four heat invariants as \( (M, g) \), at most one of which is Sol (resp. \( \mathbb{SL}_{2}(\mathbb{R}) \)) equipped with a left-invariant metric. Therefore, for spaces modeled on \( SL_{2}(\mathbb{R}) \)-geometry or Sol-geometry, we are left to consider whether it is possible to prove that in either case there is only one option for the Lie group structure on the universal covering space and, if so, whether the covering metrics are isometric.

Regarding isospectral pairs that are modeled on the \( SL_{2}(\mathbb{R}) \)-geometry, by using arguments similar to those in the previous sections, we find that certain metrics with non-degenerate Ricci tensor are determined up to local isometry by their spectra.

Proposition 3.21. — Let \( (M, g) \) be a compact locally homogeneous three-manifold with Ricci tensor \( Ric \) and let \( \nu(g) = (\nu_{1}(g), \nu_{2}(g), \nu_{3}(g)) \) denote the vector of Ric-eigenvalues. Now, suppose \( (M, g) \) is modeled on the metrically maximal geometry \( SL_{2}(\mathbb{R}), SL_{2}(\mathbb{R}) \) and is such that \( Ric \) has signature \((+, -, -)\) and \( \nu_{1}(g) < -\frac{\nu_{2}(g)\nu_{3}(g)}{\nu_{2}(g)+\nu_{3}(g)} \) (after possibly rearranging the eigenvalues); that is, \( (M, g) \) is modeled on the \( SL_{2}(\mathbb{R}) \)-geometry and \( P_{2}(\nu(g)) > 0 \). If \( (M', g') \) is a compact locally homogeneous three-manifold satisfying \( a_{j}(M, g) = a_{j}(M', g') \) for \( j = 0, 1, 2, 3 \), then \( (M', g') \) is also modeled on the metrically maximal geometry \( SL_{2}(\mathbb{R}), SL_{2}(\mathbb{R}) \) and is such that \( Ric' \) has signature \((+, -, -)\) and \( \nu_{1}(g') < -\frac{\nu_{2}(g')\nu_{3}(g')}{\nu_{2}(g')+\nu_{3}(g')} \) (after possibly rearranging the eigenvalues). Furthermore, if \( P_{1}^{2}(\nu(g)) - 4P_{2}(\nu(g)) \) is negative, then \( (M, g) \) is determined up to local isometry by its first four heat invariants.

Proof. — By Corollary 3.19, \((M', g')\) must be modeled on \((Sol, Sol)\) or \((\mathbb{SL}_{2}(\mathbb{R}), \mathbb{SL}_{2}(\mathbb{R}))\). And, by Lemma 3.3(2), \( P_{2}(\nu(g)) \) is positive. Now, using Theorem 2.18, the hypothesis on the heat invariants implies \( P_{1}(\nu(g')) = P_{1}(\nu(g)) \) and \( P_{2}(\nu(g')) = P_{2}(\nu(g)) \). By Lemma 3.3(2), \( P_{2}(\nu) \leq 0 \) for a space modeled on the Sol-geometry. Therefore, we see \((M', g')\) must be modeled on the \( SL_{2}(\mathbb{R}) \)-geometry. Then, invoking Lemma 3.3(2) again, we reach the
first conclusion of the proposition. To establish the last statement, we apply Lemma 3.2 and Theorem 2.22.

We also remark that among compact Riemannian three-manifolds modeled on the Sol-geometry the spectrum encodes local geometry.

**Proposition 3.22.** — Let \((M_1, g_1)\) and \((M_2, g_2)\) be two locally homogeneous three-manifolds with Ricci tensors \(\text{Ric}_1\) and \(\text{Ric}_2\), respectively, and such that \(a_j(M_1, g_1) = a_j(M_2, g_2)\), for \(j = 0, 1, 2\). If \((M_1, g_1)\) and \((M_2, g_2)\) are both modeled on the metrically maximal geometry \((\text{Sol}, \text{Sol})\), then \((M_1, g_1)\) is locally isometric to \((M_2, g_2)\).

**Proof.** — Setting \(j = 1, 2\), we note that as \((M_j, g_j)\) is modeled on the Sol-geometry, after possibly changing the orientations \(\Omega_j\) on the Lie algebra \(\text{sol}\) used to define the corresponding Milnor map \(L_j : (\text{sol}, \langle \cdot, \cdot \rangle_j) \to (\text{sol}, \langle \cdot, \cdot \rangle_j)\) and permuting the associated eigenvectors, we may assume that there exists nonzero constants \(a\) and \(b\) such that the eigenvalues of the Milnor map \(L_j\) are given by \(\lambda_{j,1} = 2a_j^2\), \(\lambda_{j,2} = -2b_j^2\), and \(\lambda_{j,3} = 0\), and with \(a_j^2 \geq b_j^2\) [22, p. 307]. Taking into account the assumption on the heat invariants, Theorem 2.18 yields:

\[
P_1(\nu(g_1)) = -2(a_1^2 + b_1^2)^2 = -2(a_2^2 + b_2^2)^2 = P_1(\nu(g_2))
\]

\[
P_2(\nu(g_1)) = -4(a_1^2 + b_1^2)^2(a_1^2 - b_1^2)^2
\]

\[
= -4(a_2^2 + b_2^2)^2(a_2^2 - b_2^2)^2 = P_2(\nu(g_2)).
\]

Suppose that \(a_1^2 = b_1^2\). Then, by Equation (3.9), \(a_2^2 = b_2^2\). The Equation (3.8) then implies that

\[
a_1^2 = a_2^2 = b_1^2 = b_2^2.
\]

Hence, the eigenvalues of the Milnor map for \((M_1, g_1)\) and \((M_2, g_2)\) are equal. By Lemma 3.7, \((M_1, g_1)\) and \((M_2, g_2)\) are locally isometric.

When \(a_1^2 > b_1^2\), using Equations (3.8) and (3.9), we may conclude that \(a_1^2 + b_1^2 = a_2^2 + b_2^2\) and \(a_1^2 - b_1^2 = a_2^2 - b_2^2\), from which the equalities \(a_1^2 = a_2^2\) and \(b_1^2 = b_2^2\) follow. Hence, the eigenvalues of the Milnor map for \((M_1, g_1)\) and \((M_2, g_2)\) are equal, and, again, Lemma 3.7 establishes that \((M_1, g_1)\) and \((M_2, g_2)\) are locally isometric.

**Remark 3.23.** — Proposition 3.22 demonstrates that, modulo the potential ambiguity presented by spaces modeled on the \(\text{SL}_2(\mathbb{R})\)-geometry (see Corollary 3.19 and Remark 3.20), spaces modeled on the Sol-geometry are determined up to local isometry by their spectra among compact locally homogeneous three-manifolds. While the first three heat invariants are sufficient to mutually distinguish the compact three-manifold within the family.
of spaces modeled on the Sol-geometry up to universal Riemannian cover, the first four heat invariants are unable to distinguish the spaces modeled on the Sol-geometry or $\text{SL}_2(\mathbb{R})$-geometry for which $P_2(\nu) < 0$ (cf. Proposition 3.21). We believe that computing the fifth heat invariant $a_4$ for locally homogeneous three-manifolds (in a convenient fashion) will remedy this situation, an approach we will take up in a subsequent article.

3.6. The proof of Theorem 1.1

We now prove Theorem 1.1.

**Proof of Theorem 1.1.** — This follows by combining Theorems 3.11, 3.13, 3.14 and 3.16, and Propositions 3.21 and 3.22. □

4. Distinguishing manifolds modeled on the $S^2 \times \mathbb{R}$-geometry

The goal of this section is to establish Corollary 1.3 which states that, among locally homogeneous three-manifolds, a three-manifold modeled on $(S^2 \times \mathbb{R}, \text{Isom}(S^2 \times \mathbb{E})^0)$ is uniquely determined by its spectrum. The result follows immediately from the following proposition.

**Proposition 4.1.** — Fix $k > 0$. Isospectral compact locally symmetric spaces locally isometric to $S^2_k \times \mathbb{E}$ are isometric.

Before proving Proposition 4.1 we provide an argument for Corollary 1.3.

**Proof of Corollary 1.3.** — Let $(M, g)$ be a compact locally symmetric three-manifold whose Riemannian universal cover is $S^2_k \times \mathbb{E}$. If $(M', g')$ is a compact locally homogeneous three-manifold isospectral to $(M, g)$, then Theorem 1.1 implies that $(M', g')$ is also locally isometric to $S^2_k \times \mathbb{E}$. Then, by Proposition 4.1, we see $(M, g)$ and $(M', g')$ are isometric. □

In order to prove Proposition 4.1, we first describe the compact quotients of $S^2_k \times \mathbb{E}$ up to isometry (cf. [36]). Given a real number $v$, define isometries $\tau_v, R_v \in \text{Isom}(\mathbb{R})$ by $\tau_v(x) = x + v$ and $R_v(x) = 2v - x$ for each $x \in \mathbb{R}$. Geometrically, $\tau_v$ is a translation by $v$ and $R_v$ is a reflection fixing $v$. Let $v \in \mathbb{R}$ be positive. For each integer $1 \leq i \leq 4$, define subgroups $\Gamma_i(v)$ of $\text{Isom}(S^2 \times \mathbb{E}) = \text{Isom}(S^2) \times \text{Isom}(\mathbb{E})$ as follows:

$\Gamma_1(v) = \langle (I, \tau_v) \rangle$  \hspace{1cm} $\Gamma_2(v) = \langle (-I, \tau_v) \rangle$

$\Gamma_3(v) = \langle (-I, R_0), (-I, R_v) \rangle$  \hspace{1cm} $\Gamma_4(v) = \langle (-I, I), (I, \tau_v) \rangle$. 

\text{ANNALES DE L'INSTITUT FOURIER}
The groups \( \Gamma_i(v) \) act isometrically, properly discontinuously, and freely on \( X := S_k^2 \times \mathbb{E} \). Let \( M_i(k,v) \) denote the compact locally symmetric manifold defined by \( M_i(k,v) := \Gamma_i(v) \setminus X \). Up to diffeomorphism, one can see that \( M_1(k,v) \) is \( S_k^2 \times S_1 \), \( M_2(k,v) \) is the non-trivial \( S_1 \)-bundle over \( \mathbb{RP}^2 \), \( M_3(k,v) \) is \( \mathbb{RP}^2 \# \mathbb{RP}^2 \) and \( M_4(k,v) \) is \( \mathbb{RP}^2 \times S_1 \). We omit the proof of the following well-known proposition (cf. [36]).

**Proposition 4.2.** — If \((M,g)\) is a compact locally symmetric space with universal Riemannian covering \( S_k^2 \times \mathbb{E} \), then there exists a unique positive real number \( v \) and a unique integer \( 1 \leq i \leq 4 \) such that \((M,g)\) is isometric to \( M_i(k,v) \).

**Lemma 4.3.** — The volumes of compact locally symmetric spaces with universal Riemannian covering \( S_k^2 \times \mathbb{E} \) are given by

\[
\text{vol}(M_1(k,v)) = \text{vol}(M_2(k,v)) = \text{vol}(M_3(k,v)) = 2 \text{vol}(M_4(k,v)) = \frac{4\pi v}{k}.
\]

**Proof.** — The set \( S_k^2 \times [0,v) \) is a fundamental domain for the actions of \( \Gamma_1(v) \) and \( \Gamma_2(v) \) on \( S_k^2 \times \mathbb{R} \). Therefore \( \text{vol}(M_1(k,v)) = \text{vol}(M_2(k,v)) = \text{vol}(S_k^2 \times [0,v)) = \frac{4\pi v}{k} \). The group \( \Gamma_1(v) \) is an index two subgroup of \( \Gamma_4(v) \). Therefore \( M_1(k,v) \) double covers \( M_4(k,v) \) whence \( 2 \text{vol}(M_4(k,v)) = \text{vol}(M_1(k,v)) \). Note that since \( R_v \circ R_0 = \tau_{2v} \),

\[
\Gamma_3(v) = \langle (-I, R_0), (-I, R_v) \rangle = \langle (-I, R_0), (I, \tau_{2v}) \rangle.
\]

It follows that \( \Gamma_1(2v) \) is an index two subgroup of \( \Gamma_3(v) \) whence

\[
2 \text{vol}(M_3(k,v)) = \text{vol}(M_1(k,2v)) = \frac{8\pi v}{k},
\]

concluding the proof. \( \square \)

For each positive real number \( v \) and integer \( 1 \leq i \leq 4 \), let \( \mathcal{E}_i(k,v) \) denote the set of eigenvalues of the Laplace–Beltrami operator associated to \( M_i(k,v) \). These eigenvalue sets are characterized in the next Lemma. The proof is based on a few facts that we now describe (cf. [5, 9]).

**Fact 1.** — If \( \pi : X \to M \) is a Riemannian covering, then \( \lambda \in \mathbb{R} \) is an eigenvalue for \( M \) if and only if \( \lambda \) is an eigenvalue for \( X \) whose eigenspace contains eigenfunctions invariant under the deck group of \( \pi \).

**Fact 2.** — If \( M \times N \) is a Riemannian product, then eigenfunctions for \( M \times N \) with eigenvalue \( \lambda \) are linear combinations of products of eigenfunctions for \( M \) and \( N \) whose eigenvalues sum to \( \lambda \).

**Fact 3.** — The set of eigenvalues for \( S_k^2 \) is given by \( \{m(m+1)k \mid m \in \mathbb{Z}_{\geq 0} \} \). The eigenfunctions corresponding to an eigenvalue \( m(m+1) \) are the
restrictions to $S^2$ of harmonic homogeneous degree $m$ polynomial functions on $\mathbb{R}^3$.

**Fact 4.** — For each $\lambda \in \mathbb{R}$, the nonnegative real number $\lambda^2 \in \mathbb{R}$ is an eigenvalue for $E$ with corresponding eigenspace $E_{\lambda^2} := \{a \cos(\lambda t) + b \sin(\lambda t) \mid (a, b) \in \mathbb{R}^2\}$.

**Lemma 4.4.** — For fixed $k, v > 0$, define $F : \mathbb{Z}_{\geq 0} \times \mathbb{Z}_{\geq 0} \to \mathbb{R}$ by $F(m, n) = m(m + 1)k + \pi^2 v^{-2} n^2$. The set of eigenvalues of the Laplace–Beltrami operator for a compact locally symmetric space with universal Riemannian covering $S^2_k \times \mathbb{E}$ are given by

1. $\mathcal{E}_1(k, v) = \{F(m, n) \mid (m, n) \in \mathbb{Z}_{\geq 0} \times \mathbb{Z}_{\geq 0} \text{ and } n \equiv 0 \mod 2\}$,
2. $\mathcal{E}_2(k, v) = \{F(m, n) \mid (m, n) \in \mathbb{Z}_{\geq 0} \times \mathbb{Z}_{\geq 0} \text{ and } m \equiv 0 \mod 2\}$,
3. $\mathcal{E}_3(k, v) = \{F(m, n) \mid (m, n) \in \mathbb{Z}_{\geq 0} \times \mathbb{Z}_{\geq 0} \}$, and
4. $\mathcal{E}_4(k, v) = \{F(m, n) \mid (m, n) \in \mathbb{Z}_{\geq 0} \times \mathbb{Z}_{\geq 0} \text{ and } m \equiv n \equiv 0 \mod 2\}$.

**Proof.** — By Facts 1-4, for each integer $1 \leq i \leq 4$, $\mu \in \mathcal{E}_i(k, v)$ if and only if there exist $m \in \mathbb{Z}$, $\lambda \in \mathbb{R}$, a harmonic homogeneous degree $m$ polynomial function $\phi(x)$, and a function $f(t) \in E_{\lambda^2}$ such that $\mu = m(m+1)k + \lambda^2$ and such that the function $G(x, t) := \phi(x) \cdot f(t)$ is invariant under the action of $\Gamma_i(v)$.

Use Fact 4 to verify that a function $f \in E_{\lambda^2}$ satisfies $f \circ \tau_v = f$ (respectively, $f \circ \tau_f = -f$) if and only if there exists an even (respectively, odd) integer $n \in \mathbb{Z}$ such that $\lambda^2 = \pi^2 v^{-2} n^2$.

The four eigenvalue sets are now determined by the following invariance requirements of a function of the form $G(x, t) = \phi(x) \cdot f(t)$ as described above.

**Invariance under $\Gamma_1(v)$**. — The function $G(x, t)$ is $\Gamma_1(v)$ invariant if and only if $f \circ \tau_v = f$.

**Invariance under $\Gamma_2(v)$**. — The function $G(x, t)$ is $\Gamma_2(v)$ invariant if and only if (1) the degree of $\phi$ is even and $f \circ \tau_v = f$ or (2) the degree of $\phi$ is odd and $f \circ \tau = -f$.

**Invariance under $\Gamma_3(v)$**. — Recall that $\Gamma_3(v) = \langle (-I, R_0), (I, \tau_{2v}) \rangle$. Hence, the function $G(x, t)$ is $\Gamma_3(v)$ invariant if and only if $\phi(x) \cdot f(t) = \phi(-x) \cdot f(-t)$ and $f \circ \tau_{2v} = f$. The former equality holds provided that $f(t)$ is a multiple of $\cos(\lambda t)$ (respectively, $\sin(\lambda t)$) when $\phi(x)$ has even (respectively, odd) degree. The latter equality holds provided that there exists an even integer $j$ such that $\lambda^2 = \pi^2 (2v)^{-2} j^2$, or equivalently, there exists an integer $n$ such that $\lambda^2 = \pi^2 v^{-2} n^2$.

**Invariance under $\Gamma_4(v)$**. — The function $G(x, t)$ is $\Gamma_4(v)$ invariant provided that $\phi(x) \cdot f(t) = \phi(-x) \cdot f(t)$ and $f \circ \tau_v = f$. As above, the former
Proof of Proposition 4.1. — Isospectral manifolds have equal volumes and, by Lemma 4.3, the compact quotients of $\mathbb{S}^2_k \times \mathbb{E}$ of equal volume are $M_1(k,v)$, $M_2(k,v)$, $M_3(k,v)$ and $M_4(k,2v)$. Therefore, it suffices to prove that for each pair of positive real numbers $k,v \in \mathbb{R}$, the sets $\mathcal{E}_1(k,v)$, $\mathcal{E}_2(k,v)$, $\mathcal{E}_3(k,v)$, and $\mathcal{E}_4(k,2v)$ are mutually distinct.

Without loss of generality, we can rescale the metrics so that $k=1$ and use Lemma 4.4 to deduce

$$\mathcal{E}_1(1,v) = \{F(m,n) \mid (m,n) \in \mathbb{Z}_{\geq 0} \times \mathbb{Z}_{\geq 0} \text{ and } n \equiv 0 \mod 2\}$$

$$\mathcal{E}_2(1,v) = \{F(m,n) \mid (m,n) \in \mathbb{Z}_{\geq 0} \times \mathbb{Z}_{\geq 0} \text{ and } m \equiv n \mod 2\}$$

$$\mathcal{E}_3(1,v) = \{F(m,n) \mid (m,n) \in \mathbb{Z}_{\geq 0} \times \mathbb{Z}_{\geq 0}\}$$

$$\mathcal{E}_4(1,2v) = \{F(m,n) \mid (m,n) \in \mathbb{Z}_{\geq 0} \times \mathbb{Z}_{\geq 0} \text{ and } m \equiv 0 \mod 2\}.$$

As $F(m,n)$ is monotonically increasing in $m$ and $n$, the smallest positive element of each of these sets belong to the following subsets:

$$\{F(1,0), F(0,2)\} = \{2, 4\pi^2v^{-2}\} \subset \Lambda_1(1,v)$$

$$\{F(0,2), F(1,1), F(2,0)\} = \{4\pi^2v^{-2}, 2 + \pi^2v^{-2}, 6\} \subset \Lambda_2(1,v)$$

$$\{F(0,1), F(1,0)\} = \{\pi^2v^{-2}, 2\} \subset \Lambda_3(1,v)$$

$$\{F(0,1), F(2,0)\} = \{\pi^2v^{-2}, 6\} \subset \Lambda_4(1,2v).$$

We complete the proof in the following six steps.

Step 1. Showing $\mathcal{E}_1(1,v) \neq \mathcal{E}_2(1,v).$ — If $2 = 4\pi^2v^{-2}$, then $F(m,n) = m(m+1) + n^2/2$. In this case, $F(1,1) = 5/2$ is a member of $\mathcal{E}_2(1,v)$, but not of $\mathcal{E}_1(1,v)$. If $2 \neq 4\pi^2v^{-2}$, use the subsets above to conclude that either the smallest or second smallest positive elements in these sets differ.

Step 2. Showing $\mathcal{E}_1(1,v) \neq \mathcal{E}_3(1,v).$ — Use the subsets above to conclude that either the smallest or second smallest positive elements in these sets differ.

Step 3. Showing $\mathcal{E}_1(1,v) \neq \mathcal{E}_4(1,2v).$ — If $2 = \pi^2v^{-2}$, then $F(m,n) = m(m+1) + 2n$. In this case, $F(4,1) = 22$ is a member of $\mathcal{E}_4(1,2v)$ but not of $\mathcal{E}_1(1,v)$. If $2 \neq \pi^2v^{-2}$, use the subsets above to conclude that the smallest positive elements in these sets differ.

Step 4. Showing $\mathcal{E}_2(1,v) \neq \mathcal{E}_3(1,v).$ — Use the subsets above to conclude that the smallest positive elements in these sets differ.

Step 5. Showing $\mathcal{E}_2(1,v) \neq \mathcal{E}_4(1,2v).$ — If $6 = \pi^2v^{-2}$, then $F(m,n) = m(m+1) + 6n^2$. In this case, $F(5,1) = 36$ is a member of $\mathcal{E}_4(1,v)$ but
not of $E(1, 2v)$. If $6 \neq \pi^2 v^{-2}$, use the subsets above to conclude that the smallest positive elements in these sets differ.

Step 6. Showing $E(1, v) \neq E(1, 2v)$. — If $2 = \pi^2 v^{-2}$, then $F(m, n) = m(m + 1) + 2n^2$. In this case, $F(1, 2) = 10$ is a member of $E(1, v)$ but not of $E(1, 2v)$. If $2 \neq \pi^2 v^{-2}$, use the subsets above to conclude that the smallest positive elements in these sets differ. □
