# DECOMPOSITION IN THE LARGE OF TWO-FORMS OF CONSTANT RANK 

by Ibrahim DIBAG

## 0 . Introduction.

"Whether a vector-bundle admits a 2-form of constant rank" has been an important question in algebraic topology ; and a good deal of research $(4,5,10)$ has been done on the subject. In this thesis we shall take, apriori, a vector-bundle that does admit such a 2 -form, $w$, of constant rank $2 s$. We shall then show that, $w$, locally decomposes into a sum : $w=y_{1} \wedge y_{s+1}+y_{2} \wedge y_{s+2}+\cdots+y_{s} \wedge y_{2 s}$ of products of linearly-independent 1 -forms $\left(y_{i}\right)$ on E . The main task of the thesis is to find necessary and sufficient conditions for, $w$, to have a global such decomposition.

We shall define a $2 s$-dimensional sub-bundle $S_{w}$ of $E$ on which, $w$, can be regarded as a 2 -form of maximal rank; and a necessary condition for, $w$, to decompose globally is that $\mathrm{S}_{\boldsymbol{w}}$ is a trivial (product) bundle.

Using the triviality of $\mathrm{S}_{w}$ we shall represent $w$, as a map $w_{1}$ : $\mathrm{B} \rightarrow \mathrm{I}_{s}$; where B is the base-space, and $\mathrm{I}_{s}=\mathrm{SO}(2 s) / \mathrm{U}(s)$ is the homogenous space ; and, $w$, decomposes globally if and only if $w_{1}$ lifts to $\mathrm{SO}(2 s)$.

We shall then investigate the integercohomology, $\mathrm{H}^{*}\left(\mathrm{I}_{s} ; \mathrm{Z}\right)$, of $\mathrm{I}_{s}$; and the cohomology-mapping

$$
p^{*}: \mathrm{H}^{*}\left(\mathrm{I}_{s} ; \mathrm{Z}\right) \rightarrow \mathrm{H}^{*}(\mathrm{SO}(2 s) ; \mathrm{Z})
$$

induced by the projection $p: \mathrm{SO}(2 s) \rightarrow \mathrm{I}_{s}$. We shall deduce that:

1) $\mathrm{H}^{*}\left(\mathrm{I}_{s} ; \mathrm{Z}\right)$ is, additively, generated by the duals of normal cells $\left[2 i_{1} ; 2 i_{2} ; \cdots ; 2 i_{k}\right.$ ] for $s>i_{1}>i_{2}>\cdots>i_{k} \geqslant 1$ and the zero-cell [0].
2) $p^{*}\left[2 i_{1} ; 2 i_{2} ; \cdots ; 2 i_{k}\right]^{*}$ is of order 2 in $\mathrm{H}^{*}(\mathrm{SO}(2 s) ; \mathrm{Z})$. From these two statements will follow the theorem that : "A necessary condition for the liftability of $w_{1}$ is that Image of $w_{1}^{*} \subset$ Subgroup of elements of $H^{*}(B: Z)$ of order 2 " and the corollary that :
"If $\mathrm{H}^{*}(\mathrm{~B} ; \mathrm{Z})$ does not have any 2-torsion ; then a necessary condition for the liftability of $w_{1}$ is $w_{1}^{*}=0$.

These results will then be applied to some special cases, and a full discussion will be given of the existence and decomposability of 2 -forms of constant rank on i) spheres, ii) real, and iii) complexprojective spaces.

## 1. Fiber-bundle structures over two-forms of rank $2 s$.

### 1.1. Définitions and notation :

Let E be a real $n$-dimensional inner-product space ; and as usual, identify E with its dual $\mathrm{E}^{*}$ through the metric.

Then it is well known (e.g. refer to [9]) that :
i) Any 2 -form, w, on E decomposes into

$$
w=y_{1} \wedge y_{s+1}+\cdots+y_{s} \wedge y_{2 s}
$$

a sum of products of linearly-independent vectors $\left(y_{i}\right)$ of E .
ii) The number of terms in any such decomposition is unique ; and is called the "rank" of $w$.

Thus if $\widetilde{\mathrm{V}}_{2 s}(\mathrm{E})=$ manifold of ordered $2 s$-tuplets of linearlyindependent vectors in E .
$\widetilde{\mathrm{A}}_{s}(\mathrm{E})=$ Set of 2 -forms on E of rank $2 s$.
We can define $\widetilde{f_{s}}: \widetilde{\mathrm{V}}_{2 s}(\mathrm{E}) \rightarrow \widetilde{\mathrm{A}}_{s}(\mathrm{E})$ by

$$
\left(y_{1}, y_{2}, \ldots, y_{2 s}\right) \mapsto y_{1} \wedge y_{s+1}+\cdots+y_{s} \wedge y_{2 s}
$$

and by the above, $\tilde{f_{s}}$ is "onto". Also, the real-symplectic group, $\mathrm{Sp}(s ; \mathrm{R})$ acts freely and transitively on the fibers of $\widetilde{f_{s}}$; and thus $\widetilde{f_{s}}$ factors through the orbit-space, $\widetilde{\mathrm{V}}_{2 s}(\mathrm{E}) / \mathrm{Sp}(s ; \mathrm{R})$, in a bijective fashion.

### 1.2. The Principal $\mathrm{S} p(s ; \mathrm{R})$-bundle : $\widetilde{\mathrm{V}}_{2 s}(\mathrm{E})\left(\widetilde{\mathrm{A}}_{s}(\mathrm{E}) ; \mathrm{S} p(s ; \mathrm{R})\right)$

1.2.1. Lemma. - The map $\widetilde{f_{s}}: \widetilde{\mathrm{V}}_{2 s}(\mathrm{E}) \rightarrow \widetilde{\mathrm{A}}_{s}(\mathrm{E})$ admits a local cross-section.

Note : In the following proof, we shall, for convenience of notation, take the definition of $\widetilde{f_{s}}$ to be :

$$
\widetilde{f_{s}}\left(y_{1}, \ldots, y_{2 s}\right)=y_{1} \wedge y_{2}+\cdots+y_{2 s-1} \wedge y_{2 s}
$$

Proof. - Choose a basis $\left(e_{1}, e_{2}, \ldots, e_{n}\right)$ of E. Then any $w \in \Lambda^{2} \mathrm{E}$ can be written as $w=\sum_{i<j} a_{i j}(w) e_{i} \wedge e_{j}$ where $a_{i j}: \Lambda^{2} \mathrm{E} \rightarrow \mathrm{R}^{1}$ are continuous functions on $\Lambda^{2} \mathrm{E}$.
$\mathrm{Q}_{r}=\left(w \in \mathrm{~A}_{r}(\mathrm{E}) / a_{12}(w) \neq 0\right)$ is an open subset of $\widetilde{\mathrm{A}}_{r}(\mathrm{E})$ for $1 \leqslant r \leqslant s$.

$$
\mathrm{S}_{2 r}=\widetilde{f}_{r}^{-1}\left(\mathrm{Q}_{r}\right) \subset \mathrm{V}_{2 r}(\mathrm{E}) \quad ; \quad \widetilde{f_{r}}: \mathrm{S}_{2 r} \rightarrow \mathrm{Q}_{r}
$$

well-defined.
Let F be the subspace of E generated by $\left(e_{3}, e_{4}, \ldots, e_{n}\right)$

$$
\left(\left(y_{1}, y_{2}\right) \quad ; \quad\left(y_{3}, y_{4}, \ldots, y_{2 s}\right)\right) \mapsto\left(y_{1}, y_{2}, \ldots, y_{2 s}\right)
$$

defines a continuous map

$$
i: \mathrm{S}_{2} \times \widetilde{\mathrm{V}}_{2 s-2}(\mathrm{~F}) \rightarrow \mathrm{S}_{2 s} ; \quad \text { and } \quad\left(q ; w_{0}\right) \mapsto q+w_{0}
$$

defines a continuous map $\mathrm{B}: \mathrm{Q}_{1} \times \mathrm{A}_{s-1}(\mathrm{~F}) \rightarrow \mathrm{Q}_{s}$ and that

$$
\widetilde{f_{s}} \circ i=\mathrm{B} \circ\left(\widetilde{f_{1}} \times \widetilde{f_{s-1}}\right)
$$

Now, given $w \in Q_{s}$, we have :
$w=\left(e_{1}-\frac{a_{23}}{a_{12}} e_{3}-\cdots-\frac{a_{2 n}}{a_{12}} e_{n}\right) \wedge\left(a_{12} e_{2}+\cdots+a_{1 n} e_{n}\right)+w_{0}$ where $w_{0} \in \widetilde{\mathrm{~A}}_{s-1}(\mathrm{~F})$. Let

$$
\begin{aligned}
& y_{1}(w)=e_{1}-\frac{a_{23}}{a_{12}} e_{3}-\cdots-\frac{a_{2 n}}{a_{12}} e \\
& y_{2}(w)=a_{12} e_{2}+a_{13} e_{3}+\cdots+a_{1 n} e_{n} .
\end{aligned}
$$

Then define continuous maps :

$$
\begin{aligned}
& k_{s}: \mathrm{Q}_{s} \rightarrow \mathrm{~S}_{2} \quad \text { by } \quad k_{s}(w)=\left(y_{1}(w) ; y_{2}(w)\right) \\
& p_{s}: \mathrm{Q} \rightarrow \widetilde{\mathrm{~A}}_{s-1}(\mathrm{~F}) \quad \text { by } \quad p_{s}(w)=w_{0}
\end{aligned}
$$

By définition : $\mathrm{B}\left(\left(\widetilde{f_{1}} \circ k_{s}\right) \times p_{s}\right)=l_{d}$. We shall, now, prove by induction on $s$ that $\widetilde{f_{s}}$ admits a local cross-section. For $s=1$. Assume W.L.G. that $w \in \mathrm{Q}_{1}$. Since $\widetilde{\mathrm{A}}_{s-1}(\mathrm{~F})=0 ; p_{1}(w)=0$.

Hence, $k_{1}: \mathrm{Q}_{1} \rightarrow \mathrm{~S}_{2}$ yields the desired lifting of $\widetilde{f_{1}}$.
For $s>1$; again assume W.L.G. that $w \in \mathrm{Q}_{s}$, and that the inductive hypothesis holds for $s-1$; i.e. there exists a neighbourhood U of $p_{s}(w)$ in $\widetilde{\mathrm{A}}_{s-1}(\mathrm{~F})$ and a lifting $\mathrm{L}_{s-1}$ of $\widetilde{f}_{s-1}$ over U . Then $\mathrm{N}=p_{s}^{-1}(\mathrm{U}) \subset \mathrm{Q}_{s}$ is a neighbourhood for $w$ in $\mathrm{Q}_{s}$ and hence in $\widetilde{\mathrm{A}}_{s}(\mathrm{E})$; and

$$
\mathrm{N} \xrightarrow{k_{1} \times\left(\mathrm{L}_{s-1} \circ p_{s}\right)} \mathrm{S}_{2} \times \mathrm{V}_{2 s-2}(\mathrm{~F}) \xrightarrow{i} \mathrm{~S}_{2 s} \subset \widetilde{\mathrm{~V}}_{2 s}(\mathrm{E})
$$

yields the desired lifting $\mathrm{L}_{s}=i \circ\left(k_{1} \times\left(\mathrm{L}_{s-1} \circ p_{s}\right)\right)$ of $\widetilde{f_{s}}$ over the neighbourhood N of $w$.
Q.E.D.
1.2.2. Proposition. - $\widetilde{f_{s}}$ induces a principal $\mathrm{S} p(s ; \mathrm{R})$-bundle : $\widetilde{\mathrm{V}}_{2 s}(\mathrm{E})\left(\widetilde{\mathrm{A}}_{s}(\mathrm{E}) ; \mathrm{S} p(s ; \mathrm{R})\right)$.

Proof. - The existence of a local cross-section to $\tilde{f_{s}}$ implies that $\widetilde{\mathrm{A}}_{s}(\mathrm{E})$ and the orbit-space $\widetilde{\mathrm{V}}_{2 s}(\mathrm{E}) / \mathrm{S} p(s ; \mathrm{R})$ are homeomorphic ; and that $\widetilde{f_{s}}$ and the projection $p: \widetilde{\mathrm{V}}_{2 s}(\mathrm{E}) \rightarrow \widetilde{\mathrm{V}}_{2 s}(\mathrm{E}) / \mathrm{S} p(s ; \mathrm{R})$ can be identified. The fact that the projection, $p$, induces $a$ principal $\mathrm{S} p(s ; \mathrm{R})$-bundle follows from the fact that $\mathrm{S} p(s ; \mathrm{R})$ is a closed subgroup of $\mathrm{GL}(2 s ; \mathrm{R})$; and that the full-projection :

$$
\tilde{\mathrm{V}}_{2 s}(\mathrm{E}) \rightarrow \tilde{\mathrm{V}}_{2 s}(\mathrm{E}) / \mathrm{GL}(2 s ; \mathrm{R})=\mathrm{G}_{2 s}(\mathrm{E})
$$

$=$ Grassmann-Manifold of $2 s$-planes on E, induces a principal GL( $2 s ; \mathrm{R}$ )bundle.

### 1.3. The Principal Unitary-bundle : $\mathrm{V}_{2 s}(\mathrm{E})\left(\mathrm{A}_{s}(\mathrm{E}) ; \mathrm{U}(s)\right)$.

1.3.1. Let $\mathrm{V}_{2 s}(\mathrm{E})=$ Stiefel Manifold of orthonormal $2 s$-frames on $\mathrm{E} . \mathrm{A}_{s}(\mathrm{E})=\widetilde{f_{s}}\left(\mathrm{~V}_{2 s}(\mathrm{E})\right)=$ Manifold of "normalized" 2-forms on E of
rank 2s. $f_{s}: \mathrm{V}_{2 s}(\mathrm{E}) \rightarrow \mathrm{A}_{s}(\mathrm{E})$ the "restriction" of $\widetilde{f}_{s}$ to $\mathrm{V}_{2 s}(\mathrm{E})$.
Then, $\mathrm{U}(s)=\mathrm{Sp}(s ; \mathrm{R}) \cap \mathrm{O}(2 s)$ acts freely and transitively on the fibers of $f_{s}$; and thus $f_{s}$ factors through the orbit-space $\mathrm{V}_{2 s}(\mathrm{E}) / \mathrm{U}(s)$ in a bijective-fashion.

Lemma. - There exists a retraction $r: \tilde{V}_{2 s}(\mathrm{E}) \rightarrow \mathrm{V}_{2 s}(\mathrm{E})$ such such that $\widetilde{f_{s}}=f_{s} \circ r$ when restricted to $\widetilde{f_{s}^{-1}}\left(\mathrm{~A}_{s}(\mathrm{E})\right)$.

Sketch of Proof. - Let $y \in \mathrm{~V}_{2 s}(\mathrm{E})$; and pick any orthonormal frame $e$ in the plane of $y$. Then $y=u \circ e$ for some $u \in \mathrm{GL}(2 s ; \mathrm{R})$. Let $u=t v$ be the polar decomposition of $u$ into an orthogonal matrix $t$ and a positive-definite symmetric matrix $v$. Put $r(y)=t \circ e$. Then, independence of the definition of $r(y)$ on the frame used, and other properties of $r$ can easily be verified.

Corollary. - Let B be a topological-space and $w: \mathrm{B} \rightarrow \mathrm{A}_{s}(\mathrm{E})$ a continuous map; and $\phi: \mathrm{B} \rightarrow \widetilde{\mathrm{V}}_{2 s}(\mathrm{E})$ a lifting of $w$. Then, $r \circ \phi$ lifts $w$ to $\mathrm{V}_{2 s}(\mathrm{E})$.

### 1.3.2. Proposition. $-f_{s}$ induces a principal $\mathrm{U}(s)$-bundle :

$$
\mathrm{V}_{2 s}(\mathrm{E})\left(\mathrm{A}_{s}(\mathrm{E}) ; \mathrm{U}(s)\right) .
$$

Proof. - Let $\phi$ be a cross-section to $\widetilde{f_{s}}$ over some compact neighbourhood $\tilde{\mathrm{N}}$ of $\widetilde{\mathrm{A}}_{s}(\mathrm{E})$. Put $\mathrm{N}=\tilde{\mathrm{N}} \cap \mathrm{A}_{s}(\mathrm{E})$ and $\phi_{1}=\phi / \mathrm{N}$. Then, by the preceeding Corollary, $r \phi_{1}$ is a cross-section to $f_{s}$ over N . Define $t: \mathrm{N} \times \mathrm{U}(s) \rightarrow f_{s}^{-1}(\mathrm{~N})$ by $t(n, u)=u\left(\left(r \phi_{1}\right) n\right)$. Then, $t$, is a homeomorphism (by compactness). Hence $f_{s}$ is locally-trivial ; and thus induces a principal $\mathrm{U}(s)$-bundle.
1.4. Retraction of $\widetilde{\mathrm{A}}_{s}(\mathrm{E})$ onto $\mathrm{A}_{s}(\mathrm{E})$.

Let $\widetilde{W}_{s}=$ Set of non-singular and skew-symmetric $2 s \times 2 s$ matrices. $\mathrm{W}_{s}=$ Set of orthogonal and skew-symmetric $2 s \times 2 s$ matrices. Then, GL( $2 s ; \mathrm{R}$ ) acts on $\mathrm{W}_{s}$ by $u \circ k=u k u^{t}$ for

$$
u \in \mathrm{GL}(2 s ; \mathrm{R}) \mathrm{i} \quad \text { and } \quad k \in \widetilde{\mathrm{~W}}_{s}
$$

and the subgroup, $\mathrm{O}(2 s)$, leaves $\mathrm{W}_{s}$ invariant under this action. If
$k=g v$ is the polar-decomposition of $k \in \widetilde{W}_{s}$; then $g \in \mathrm{~W}_{s}$; and thus
$k \rightarrow g$ defines a projection $p: \widetilde{W}_{s} \rightarrow \mathrm{~W}_{s}$.
Lemma. - There exists. a continuous deformation retraction of $\widetilde{\mathrm{W}}_{s}$ onto $\mathrm{W}_{s}$ that commutes with the action of $\mathrm{O}(2 s)$.

Proof. - Define a homotopy $h_{r}: \widetilde{\mathrm{W}}_{s} \rightarrow \mathrm{~W}_{s}$ by

$$
h_{r}(g v)=g\left((1-r) v+r l_{d}\right)
$$

Then, $h_{o}=l_{d} ; h_{l}=p$; and $h_{r}$ commutes with the action of $\mathrm{O}(2 s)$.
From this Lemma we recover the following :
Proposition. - There exists a retraction $\theta: \widetilde{\mathrm{A}}_{s}(\mathrm{E}) \rightarrow \mathrm{A}_{s}(\mathrm{E})$.
Proof. - Let's first assume that $n=2 s$. Then, an orthonormal frame $e$ on E defines homeomorphisms ; $t_{e}: \widetilde{\mathrm{W}}_{s} \rightarrow \widetilde{\mathrm{~A}}_{s}(\mathrm{E})$ and $t_{e}: \mathrm{W}_{s} \rightarrow \mathrm{~A}_{s}(\mathrm{E})$ by $t_{e}(k)=\sum_{i<j} k_{i j} e_{i} \wedge e_{j}$ and $t_{e}=t_{e} / \mathrm{W}_{s}$.

A homotopy $f_{r}: \widetilde{\mathrm{A}}_{s}(\mathrm{E}) \rightarrow \mathrm{A}_{s}(\mathrm{E})$ can be defined by $f_{r}=t_{e} \circ h_{r} \circ t_{e}^{-1}$ and it is, immediately, verified that this definition is independent of the orthonormal frame used. Thus, $\theta=f_{1}$ yields the desired retraction.

For $n \geqslant 2 s$; we have the diagram :

a retraction $\theta_{p}$; and a homotopy $\left(f_{r}\right)_{p}: \tilde{\pi}^{-1}(p) \rightarrow \pi^{-1}(p)$ over each $2 s$-plane, $p \in \mathrm{G}_{2 s}(\mathrm{E})$. Then, the collections, $\theta=\left(\theta_{p}\right)_{p \in \mathrm{G}_{2 s}}(\mathrm{E})$ and $f_{r}=\left(f_{r}\right)_{p}$ yield the desired retraction and the homotopy respectively.
Q.E.D.

## 2. Decomposability of two-forms of constant rank.

### 2.1. Notations and definitions :

Let E be an $\mathrm{R}^{n}$-bundle (with a Riemannian-metric) over a connected base-space B. Let $\widetilde{\mathrm{V}}_{2 s}(\mathrm{E}), \mathrm{V}_{2 s}(\mathrm{E}), \widetilde{\mathrm{A}}_{s}(\mathrm{E}), \mathrm{A}_{s}(\mathrm{E})$ be the associated-bundles to E with fibers $\widetilde{\mathrm{V}}_{2 s}\left(\mathrm{R}^{n}\right), \mathrm{V}_{2 s}\left(\mathrm{R}^{n}\right), \widetilde{\mathrm{A}}_{s}\left(\mathrm{R}^{n}\right), \mathrm{A}_{s}\left(\mathrm{R}^{n}\right)$ respectively. A 2 -form, $w$, on E of constant rank $2 s$ is, by definition, $a$ cross-section to $\mathrm{A}_{s}(\mathrm{E})$. The maps $\widetilde{f_{s}}(\mathrm{E}): \widetilde{\mathrm{V}}_{2 s}(\mathrm{E}) \rightarrow \widetilde{\mathrm{A}}_{s}(\mathrm{E})$ and $f_{s}(\mathrm{E}): \mathrm{V}_{2 s}(\mathrm{E}) \rightarrow \mathrm{A}_{s}(\mathrm{E})$ are defined and we have the following "global" versions of Propositions 1.2.2. and 1.3.2. :

Proposition 1.2.2.* $-\widetilde{f_{s}}(\mathrm{E})$ induces a principal $\mathrm{S} p(s ; \mathrm{R})$-bundle.
Proposition 1.3.2.* $-f_{s}(\mathrm{E})$ induces a principal $\mathrm{U}(s)$-bundle.

### 2.2. Local-Decomposability and the Sub-bundle $\mathrm{S}_{\boldsymbol{w}}$ :

Definition. - A 2-form, $w$, on E of constant rank 2 s is said to be locally-decomposable iff each point $x \in \mathrm{~B}$ has a neighbourhood $\mathrm{U}_{x}$ and linearly-independent 1-forms $\left(y_{i}\right) i=1, \ldots, 2 s$ on E over $\mathrm{U}_{x}$ s.t. $w=y_{1} \Lambda y_{s+1}+\cdots+y_{s} \wedge y_{2 s}$ over $\mathrm{U}_{x}$. (Or, alternatively, there exists a cross-section, $y$, to $\widetilde{\mathrm{V}}_{2 s}(\mathrm{E})$ over $\mathrm{U}_{x}$ such that $\left.w=\widetilde{f_{s}} \circ y\right)$.

Lemma. - $A$ 2-form, $w$, of constant rank $2 s$ on E is locallydecomposable.

Proof. - Let $x \in \mathrm{~B}$; and, $c$, a cross-section to $\widetilde{f_{s}}(\mathrm{E})$ :

$$
\widetilde{\mathrm{V}}_{2 s}(\mathrm{E}) \rightarrow \widetilde{\mathrm{A}}_{s}(\mathrm{E})
$$

over a neighbourhood N of $w(x)$ in $\widetilde{\mathrm{A}}_{s}(\mathrm{E})$. Then, the composite $w^{-1}(\mathrm{~N}) \xrightarrow{w} \mathrm{~N} \xrightarrow{c} \mathrm{~V}_{2 s}(\mathrm{E})$ defines a cross-section $y=c w$ to $\widetilde{f_{s}}(\mathrm{E})$ over $w^{-1}(\mathrm{~N})$ such that $\widetilde{f_{s}} \circ y=w$.
Q.E.D.

Given a 2 -form, $w$, of constant rank $2 s$; then at each point $x \in \mathrm{~B}, w(x)$ determines a $2 s$-dimensional subspace $\mathrm{S}_{\boldsymbol{w ( x )}}$ of $\mathrm{E}_{x}$ on which it is of maximal rank ; and local decomposability of $w$, immetiately yields the following :

Proposition. - The union $\mathrm{S}_{\boldsymbol{w}}=\underset{x \in \mathrm{~B}}{ } \mathrm{~S}_{\boldsymbol{w}(\boldsymbol{x})}$ is a sub-bundle of E ; and, $w$, being a 2-form on $\mathrm{S}_{w}$ of maximal-rank determines a reduction of its structure group from $\mathrm{GL}(2 s ; \mathrm{R})$ to $\mathrm{S} p(s ; \mathrm{R})$.

This Proposition, clearly, demonstrates that the "existence of a 2-form of constant rank on E" (which is assumed apriori in the thesis) is, already, a strong condition ; and will be useful in proving non-existence theorems about 2-forms of constant rank on spheres and projective-spaces in the last-chapter.
2.3. Decomposition of 2-forms of constant rank :

Let $\widetilde{\mathrm{V}}\left(\mathrm{S}_{w}\right), \mathrm{V}\left(\mathrm{S}_{w}\right), \widetilde{\mathrm{A}}\left(\mathrm{S}_{w}\right), \mathrm{A}\left(\mathrm{S}_{w}\right)$ be the associated-bundles to $\mathrm{S}_{w}$ with fibers $\tilde{\mathrm{V}}\left(\mathrm{R}^{2 s}\right), \mathrm{V}\left(\mathrm{R}^{2 s}\right), \widetilde{\mathrm{A}}\left(\mathrm{R}^{2 s}\right), \mathrm{A}\left(\mathrm{R}^{2 s}\right)$ respectively.

Definition. -w is said to be decomposable iff

$$
w=y_{1} \wedge y_{s+1}+\cdots+y_{s} \wedge y_{2 s}
$$

for linearly-independent 1-forms $\left(y_{i}\right)$ on $E$. (Or, alternatively, the diagram : admits a lifting).

An immediate consequence of this definition is the following :
Observation. - If, w, is decomposable ; then $\mathrm{S}_{\boldsymbol{w}}$ is a trivial (product)-bundle.

Let $r: \widetilde{\mathrm{V}}\left(\mathrm{S}_{\boldsymbol{w}}\right) \rightarrow \mathrm{V}\left(\mathrm{S}_{\boldsymbol{w}}\right)$ and $\theta: \widetilde{\mathrm{A}}\left(\mathrm{S}_{\boldsymbol{w}}\right) \rightarrow \mathrm{A}\left(\mathrm{S}_{\boldsymbol{w}}\right)$ be the retractions of Sections 1.3. and 1.4. (respectively) defined globally on $S_{w}$.

Definition. - The "normalization" of, $w$, is defined to be the composite $\theta w: \mathrm{B} \xrightarrow{\boldsymbol{w}} \widetilde{\mathrm{A}}\left(\mathrm{S}_{\boldsymbol{w}}\right) \xrightarrow{\theta} \mathrm{A}\left(\mathrm{S}_{\boldsymbol{w}}\right)$ and is a "normalized" 2-form of rank 2 s. (i.e. a cross-section to $\mathrm{A}\left(\mathrm{S}_{w}\right)$ ).

Definition. - A normalized 2-form, $w$, of rank $2 s$ decomposes orthogonally iff $w=y_{1} \wedge y_{s+1}+\cdots+y_{s} \wedge y_{2 s}$ for orthonormal-frame $y=\left(y_{1}, \ldots, y_{2 s}\right)$ on $\mathrm{S}_{w}$.

Proposition. - A 2-form, w, of constant rank $2 s$ decomposes iff its normalization decomposes orthogonally.

Proof. - Suppose, $w$, decomposes. i.e. there exists a continuous map $\mathrm{L}: \mathrm{B} \rightarrow \widetilde{\mathrm{V}}\left(\mathrm{S}_{\underset{w}{ }}\right)$ such that $\widetilde{f_{s}} \circ \mathrm{~L}=w$. Since $\theta$ is a retraction ; $w \simeq \theta w$, and thus $\widetilde{f_{s}} \circ \mathrm{~L} \simeq \theta w$. Since $\widetilde{f_{s}}$ is a fibration; by the covering-homotopy-theorem ; there exists a lifting $\mathrm{T}: \mathrm{B} \rightarrow \widetilde{\mathrm{V}}\left(\mathrm{S}_{w}\right)$ of $\theta w$ to $\widetilde{\mathrm{V}}\left(\mathrm{S}_{w}\right)$ and by the "global-version" of Corollary 1.3.1. $r \mathrm{~T}$ is a lifting of $\theta w$ to $\mathrm{V}\left(\mathrm{S}_{w}\right)$. Thus, $\theta w$ decomposes orthogonally.

Conversely, suppose $\theta w$ decomposes orthogonally ; i.e. that there exists a lift $k: \mathrm{B} \rightarrow \mathrm{V}\left(\mathrm{S}_{\boldsymbol{w}}\right)$ of $\theta w$ to $\mathrm{V}\left(\mathrm{S}_{w}\right)$. Then,

$$
f_{s} \circ k=\theta w \simeq w
$$

and again, by the covering homotopy theorem, there exists a lifting of, $w$, to $\widetilde{\mathrm{V}}\left(\mathrm{S}_{w}\right)$.
Q.E.D.

By Observation 2.3., a necessary condition for $w$ to decompose is that $S_{w}$ is a trivial (product)-bundle. Let's choose a particular product representation : $\mathrm{S}_{w}=\mathrm{B} \times \mathrm{R}^{2 s}$ which gives rise to further product representations : i) $\mathrm{V}\left(\mathrm{S}_{w}\right)=\mathrm{B} \times \mathrm{V}\left(\mathrm{R}^{2 s}\right)=\mathrm{B} \times \mathrm{O}(2 s)$ and ii) $\mathrm{A}\left(\mathrm{S}_{w}\right)=\mathrm{B} \times \mathrm{A}\left(\mathrm{R}^{2 s}\right)=\mathrm{B} \times \mathrm{O}(2 s) / \mathrm{U}(s)$ and a representation of $\theta w$ as a map $w_{1}: \mathrm{B} \rightarrow \mathrm{O}(2 s) / \mathrm{U}(s)$.
$\theta w$ decomposes orthogonally iff $w_{1}$ lifts to $\mathrm{O}(2 s)$. Since B is connected and $w_{1}$ continuous ; we may, without loss of generality assume that $w_{1}(\mathrm{~B}) \subset \mathrm{I}_{s}=\mathrm{SO}(2 s) / \mathrm{U}(s)$; and then lifting $w_{1}$ to $\mathrm{O}(2 s)$ is equivalent to lifting it to $\mathrm{SO}(2 s)$. We can summarize this in a single :

Theorem. - A 2-form, $w$, of constant rank $2 s$ decomposes iff
i) $\mathrm{S}_{w}$ is a trivial (product)-bundle.
ii) The representation of its normalization as a map $w_{1}$ :

$$
\mathrm{B} \rightarrow \mathrm{I}_{s}=\mathrm{SO}(2 s) / \mathrm{U}(s)
$$

arising from any trivialization of $\mathrm{S}_{\boldsymbol{w}}$ lifts to $\mathrm{SO}(2 s)$.
The method used above was to assume the existence apriori, of a metric on E (and thus on $\mathrm{S}_{\boldsymbol{w}}$ ) ; and to show that, $w$, decomposes iff its normalization (with respect to this metric) decomposes orthogonally.

A more and invariant approach does not pre-suppose the existence of a metric on $\mathrm{S}_{\boldsymbol{w}} . w$, determines a reduction of the structure-group of $\mathrm{S}_{w}$ to $\mathrm{S} p(s ; \mathrm{R})$; and since $\mathrm{U}(s)$ is a maximal compact subgroup of $\mathrm{S} p(s ; \mathrm{R})$; it undergoes a further reduction to $\mathrm{U}(s)$; and thus $\mathrm{S}_{\boldsymbol{w}}$ admits a unique Hermitian metric. Then, $w$, becomes normalized with respect to the corresponding real-metric, and thus decomposes iff it decomposes orthogonally. The rest of the theory goes as before ; and one, again, obtains the above theorem with obvious modifications.

## 3. Cohomology of $I_{s}$.

### 3.1. Preliminaries :

Let $x \in \mathrm{P}^{n-1}$; and $\phi_{x}$ be the "reflection" through the hyperplane perpendicular to $x$; and $\phi_{0}$ the reflection corresponding to the initial point ( $1,0, \ldots, 0$ ). Then, we imbed $P^{n-1} \subset \mathrm{SO}(n)$ by $x \rightarrow \phi_{x} \phi_{0}$. We, now, list the following standard results ; and for proofs we refer the reader to [8] pp. 40-45.

Observation: i) $\mathrm{P}^{n-1} \cap \mathrm{SO}(n-1)=\mathrm{P}^{n-2}$. ii) $\mathrm{P}^{i} \circ \mathrm{P}^{j}=\mathrm{P}^{j} \circ \mathrm{P}^{i}$ and iii) $\mathrm{P}^{i} \circ \mathrm{P}^{i}=\mathrm{P}^{i} \circ \mathrm{P}^{i-1}$ in $\mathrm{SO}(n)$.

Let $\mathrm{P}^{n-1} / \mathrm{P}^{n-2}$ be the space obtained by collapsing $\mathrm{P}^{n-2}$ to a point ; and $\mathrm{SO}(n) / \mathrm{SO}(n-1)$ the left coset-space.

Lemma. - The natural-map $\mathrm{T}: \mathrm{P}^{n-1} / \mathrm{P}^{n-2} \rightarrow \mathrm{SO}(n) / \mathrm{SO}(n-1)$ is a "homeomorphism".

Proposition. - The matrix-multiplication

$$
m:\left(\mathrm{P}^{n} \times \mathrm{SO}(n) ; \mathrm{P}^{n-1} \times \mathrm{SO}(n)\right) \rightarrow(\mathrm{SO}(n+1) ; \mathrm{SO}(n))
$$

is a relative-homeomorphism.

Theorem. - $\mathrm{SO}(n)$ is a cell-complex with normal cells

$$
\left[i_{1} ; i_{2} ; \cdots ; i_{k}\right] \text { for } n>i_{1}>i_{2}>\cdots>i_{k} \geqslant 1
$$

given by

$$
\mathrm{E}^{i_{1}} \times \mathrm{E}^{i_{2}} \times \cdots \times \mathrm{E}^{i_{k}} \rightarrow \mathrm{P}^{i_{1}} \times \mathrm{P}^{i_{2}} \times \cdots \times \mathrm{P}^{i_{k}} \xrightarrow{m} \mathrm{SO}(n)
$$

and the zero-cell $[0]$; and matrix-multiplication $m$ :

$$
\mathrm{SO}(n) \times \mathrm{SO}(n) \rightarrow \mathrm{SO}(n)
$$

is a cellular-map.
3.2. Cellular Structure of $\mathrm{I}_{s}$ :

$$
\text { Observation : } \mathrm{I}_{s}=\mathrm{SO}(2 s) / \mathrm{U}(s)=\mathrm{SO}(2 s-1) / \mathrm{U}(s-1) .
$$

Proof. - Obviously, $\mathrm{SO}(2 s-1) \cap \mathrm{U}(s)=\mathrm{U}(s-1)$ and

$$
\mathrm{SO}(2 s-1) \circ \mathrm{U}(s)=\mathrm{SO}(2 s)
$$

by a dimension argument. Thus,

$$
\mathrm{I}_{s}=\mathrm{SO}(2 s-1) \circ \mathrm{U}(s) / \mathrm{U}(s)=\mathrm{SO}(2 s-1) / \mathrm{U}(s-1)
$$

Q.E.D.

Let $\overline{\mathrm{P}}^{2 s+1}$ and $\overline{\mathrm{P}}^{2 s}$ denote the images of $\mathrm{P}^{2 s+1}$ and $\mathrm{P}^{2 s}$ under the projections $\mathrm{SO}(2 s+2) \rightarrow \mathrm{I}_{s+1}$ and $\mathrm{SO}(2 s+1) \rightarrow \mathrm{I}_{s+1}$ respectively. We, then, have the following :

$$
\text { Lemma. }-\overline{\mathrm{P}}^{2 s+1}=\overline{\mathrm{P}}^{2 s}
$$

Proof. - It is an immediate consequence of the fact that the "composite" $\mathrm{P}^{2 s+1} \subset \mathrm{SO}(2 s+2) \rightarrow \mathrm{I}_{s+1}$ factors through $\mathrm{P}_{s}(\mathrm{C})$; and that $\mathrm{P}^{2 s} \subset \mathrm{P}^{2 s+1} \rightarrow \mathrm{P}_{s}(\mathrm{C})$ is "onto".
Q.E.D.

Let $v: \mathrm{SO}(2 s) \times \mathrm{I}_{s} \rightarrow \mathrm{I}_{s}$ be the action of $\mathrm{SO}(2 s)$ on $\mathrm{I}_{s}$. Then, we obtain the analogue of Proposition 3.1. for $I_{s}$ :

[^0]which in turn becomes the key in the proof of the following

ThEOREM. $-\mathrm{I}_{s}$ is a cell-complex consisting of even-dimensional normal-cells $\left[2 i_{1} ; 2 i_{2} ; \cdots ; 2 i_{k}\right]$ for $s>i_{1}>i_{2}>\cdots>i_{k} \geqslant 1$, given by

$$
\mathrm{E}^{2 i_{1}} \times \cdots \times \mathrm{E}^{2 i_{k}} \rightarrow \mathrm{P}^{2 i_{1}} \times \cdots \times \mathrm{P}^{2 i_{k}} \xrightarrow{m} \mathrm{SO}(2 s) \xrightarrow{\text { proj}^{n}} \mathrm{I}_{s}
$$

and the zer-cell $[\mathrm{O}]$; and the action-map $v: \mathrm{SO}(2 s) \times \mathrm{I}_{s} \rightarrow \mathrm{I}_{s}$ is cellular.

Proof. - We prove the theorem by induction on $s$.
For $s=1 ; \mathrm{I}_{1}$ is just the zero-cell O ; and thus $v: \mathrm{SO}(2) \times \mathrm{I}_{1} \rightarrow \mathrm{I}_{1}$ is, obviously, cellular. By the preceding proposition, $\mathrm{I}_{s+1}$ is the adjunction-space : $\mathrm{I}_{s^{+1}}=\mathrm{I}_{s} v_{v}\left(\mathrm{P}^{2 s} \times \mathrm{I}_{s}\right)$. We, now, apply the following standard Lemma : "If $K$ and $L$ ' are cell-complexes; $L$ a subcomplex of K and $v: \mathrm{L} \rightarrow \mathrm{L}^{\prime}$ a cellular-map ; then the adjunction-space, $\mathrm{K}{ }{ }_{v} \mathrm{~L}^{\prime}$ is a cell-complex having $L^{\prime}$ as a subcomplex ; and the images of the cells of ( $\mathrm{K}-\mathrm{L}$ ) as the remaining cells" with

$$
\mathrm{K}=\mathrm{P}^{2 s} \times \mathrm{I}_{s} \quad ; \quad \mathrm{L}=\mathrm{P}^{2 s-1} \times \mathrm{I}_{s} \quad ; \quad \mathrm{L}^{\prime}=\mathrm{I}_{s}
$$

By the inductive hypothesis, $v: \mathrm{SO}(2 s) \times \mathrm{I}_{s} \rightarrow \mathrm{I}_{s}$; and hence its restriction to the subcomplex, $\mathrm{P}^{2 s-1} \times \mathrm{I}_{s}$, is cellular ; and thus we deduce that, $\mathrm{I}_{s+1}$, is a cell-complex having $\mathrm{I}_{s}$ as a subcomplex ; and the $v$-images of the cells of $\left(\mathrm{P}^{2 s}-\mathrm{P}^{2 s-1}\right) \times \mathrm{I}_{s}$ as the remaining cells. By the inductive-hypothesis, the cells of $\mathrm{I}_{s}$ are normal cells [2i $i_{1} ; \cdots ; 2 i_{k}$ ] for $s>i_{1}>\cdots>i_{k} \geqslant 1$, and the zero-cell [O]; and the $v$-images of the cells of $\left(\mathrm{P}^{2 s}-\mathrm{P}^{2 s-1}\right) \times \mathrm{I}_{s}$ are normal-cells $\left[2 s ; 2 i_{2} ; \cdots ; 2 i_{k}\right]$ for $s>i_{2}>\cdots>i_{k} \geqslant 1$. The proof will be complete once we prove that : v: $\mathrm{SO}(2 s+2) \times \mathrm{I}_{s+1} \rightarrow \mathrm{I}_{s+1}$ is cellular ; and this is done in five steps :
i) $v: \mathrm{P}^{2 s} \times \mathrm{I}_{s} \rightarrow \mathrm{I}_{s+1}$ is cellular.
ii) $v: \mathrm{SO}(2 s+1) \times \mathrm{I}_{s} \rightarrow \mathrm{I}_{s+1}$ is cellular.
iii) $v: S O(2 s+1) \times \mathrm{I}_{s+1} \rightarrow \mathrm{I}_{s+1}$ is cellular.
iv) $v: \mathrm{P}^{2 s+1} \times \mathrm{I}_{s+1} \rightarrow \mathrm{I}_{s+1}$ is cellular.
v) $v: \mathrm{SO}(2 s+2) \times \mathrm{I}_{s+1} \rightarrow \mathrm{I}_{s+1}$ is cellular.

Only iv) has a non-trivial proof which can be outlined as follows :

Proof of $i v$ ). - By iii) the restriction of, $v$, to the subcomplex, $\mathrm{P}^{2 s} \times \mathrm{I}_{s+1}$ of, $\mathrm{P}^{2 s+1} \times \mathrm{I}_{s+1}$, is cellular ; and thus it suffices to prove that :

$$
v\left(\mathrm{P}^{2 s+1} ;\left(\mathrm{I}_{s+1}\right)^{2 q}\right) \subset\left(\mathrm{I}_{s+1}\right)^{2(s+q)}
$$

Let $s+1>i_{1}>i_{2}>\cdots>i_{k} \geqslant 1$ and $i_{1}+i_{2}+\cdots+i_{k}=q$

$$
\begin{aligned}
& v\left(\mathrm{P}^{2 s+1} ; \overline{\mathrm{P}^{2 i_{1}} \times \cdots \times \mathrm{P}^{2 i_{k}}}\right) \\
& =\overline{\mathrm{P}^{2 i_{1}} \times \cdots \times \mathrm{P}^{2 i_{k}} \times \mathrm{P}^{2 s+1}}=\overline{\mathrm{P}^{2 s+1} \times \mathrm{P}^{2 i_{1}} \times \cdots \times \mathrm{P}^{2 i_{k}}} \\
& =v\left(\mathrm{P}^{2 i_{1}} \times \cdots \times \mathrm{P}^{2 i_{k}} ; \overline{\mathrm{P}}^{2 s}\right)=v\left(\mathrm{P}^{2 i_{1}} \times \cdots \times \mathrm{P}^{2 i_{k}} ; \overline{\mathrm{P}}^{2 s+1}\right) \\
& =v\left(\mathrm{P}^{2 s} ; \overline{\mathrm{P}^{2 i_{1}} \times \mathrm{P}^{2 i_{2}} \times \cdots \times \mathrm{P}^{2 i_{k}}}\right) \subset v\left((\mathrm{SO}(2 s+1))^{2 s} ;\left(\mathrm{I}_{s+1}\right)^{2 q}\right) \\
& \left.\subset\left(\mathrm{I}_{s+1}\right)^{2(s+q)} \text { by Part iii}\right) .
\end{aligned}
$$

Q.E.D.

Corollary. - The projection $p: \mathrm{SO}(2 s) \rightarrow \mathrm{I}_{s}$ is cellular ; and maps normal cells $\left[2 i_{1} ; 2 i_{2} ; \cdots ; 2 i_{k}\right]$ of $\mathrm{SO}(2 s)$ onto normal cells $\left[2 i_{1} ; 2 i_{2} ; \cdots ; 2 i_{k}\right.$ ] of $\mathrm{I}_{s}$. The images of the remaining cells, i.e. $\left[j_{1} ; j_{2} ; \cdots ; j_{k}\right.$ ] where $j_{t}$ is odd for some $1 \leqslant t \leqslant k$ are contained in a skeleton of lower dimension.

### 3.3. Integer-Cohomology of $\mathrm{I}_{s}$ and the Lifting Problem :

Since $I_{s}$ is a cell-complex consisting of even dimensional cells only ; the co-boundary operator is identically zero ; and hence the $2 q^{\text {th }}$-cohomology group $\mathrm{H}^{2 q}\left(\mathrm{I}_{s} ; \mathrm{Z}\right)$ coincides with $2 q^{\text {th }}$-cochains, $\mathrm{C}^{2 q}\left(\mathrm{I}_{s} ; \mathrm{Z}\right)$, which is the free abelian group generated by the duals $\left[2 i_{1} ; \cdots ; 2 i_{k}\right]^{*}$ of normal cells $\left[2 i_{1} ; \cdots ; 2 i_{k}\right.$ ] for $q=i_{1}+\cdots+i_{k}$.

Proposition. - Image $p^{*} \subset$ Subgroup of elements of

$$
\mathrm{H}^{*}(\mathrm{SO}(2 s) ; \mathrm{Z})
$$

of order 2.
Proof. - By the above ; $p^{*}\left[2 i_{1} ; \cdots ; 2 i_{k}\right]^{*}=\left[2 i_{1} ; \cdots ; 2 i_{k}\right]^{*}$ and $2\left[2 i_{1} ; \cdots ; 2 i_{k}\right]^{*}=\delta\left[2 i_{1}-1 ; \cdots ; 2 i_{k}\right]^{*}$ in $\operatorname{SO}(2 s)$.

Theorem. - A necessary condition for the lifting of the diagram :

is that :
Image $w_{1}^{*} \subset$ Subgroup of elements of $\mathrm{H}^{*}(\mathrm{~B} ; \mathrm{Z})$ of order 2.
Corollary. - If $\mathrm{H}^{*}(\mathrm{~B} ; \mathrm{Z})$ contains no 2-torsion ; then a necessary condition for the liftability of $w_{1}$ is that $w_{1}^{*}=0$.

## 4. Applications.

### 4.1. Lower-Dimensional Spaces :

We now, combine Theorems 2.3. and 3.4. with elementary obstruction theory to obtain the following :

Proposition. - Let, w, be a 2-form of constant rank $2 s(s>1)$ on an $\mathrm{R}^{n}$-bundle E over a connected base-space B whose cohomology vanishes in dimensions greater than or equal to four. Necessary and sufficient conditions for, $w$, to decompose are i) $\mathrm{S}_{w}$ is a trivial (product)-bundle ; and ii) $2 w_{1}^{*}=0$ in $\mathrm{H}^{2}(\mathrm{~B} ; \mathrm{z})$ where

$$
i \in \mathrm{H}^{2}\left(\mathrm{I}_{s} ; \mathrm{Z}\right)=\mathrm{Z}
$$

is the generator and $w_{1}$ is the representation of, $w$, arising from any trivialization of $\mathrm{S}_{\boldsymbol{w}}$.

When $B$ is an orientable 3-manifold, the tangent-bundle $T(B)$ of $B$ is trivial ; and $S_{w}$ is the pull-back of the tangent-bundle $T\left(S^{2}\right)$ of the 2-sphere by the Gauss-Map $\mathrm{P}: \mathrm{B} \rightarrow \mathrm{S}^{2}$; and thus the first Chern-Class, $c_{1}\left(\mathrm{~S}_{w}\right)=2 \mathrm{P}^{*}(i)$, where $i \in \mathrm{H}^{2}\left(\mathrm{~S}^{2} ; \mathrm{Z}\right)$ is the generator. Also by Alexander Duality, $2 \mathrm{P}^{*}(i)=0$ iff $\mathrm{P}^{*}(i)=0$. Applying Theorem 2.3. yields the observation - A nowhere-vanishing 2-form, $w$, on an orientable 3-manifold decomposes iff $\mathrm{P}^{*}(i)=0$.

If we further specialize by taking $B$ to be an open connected domain in $\mathrm{R}^{3}$ and use the Hopf-Classification Theorem that $[\mathrm{P}] \rightarrow \mathrm{P}^{*}(i)$ is an isomorphism : $\left[\mathrm{B} ; \mathrm{S}^{2}\right] \rightarrow \mathrm{H}^{2}(\mathrm{~B} ; \mathrm{Z})$; we obtain :

Corollary. - A nowhere-vanishing 2-form, w, on an open connected domain B of $\mathrm{R}^{3}$ decomposes iff the Gauss-Map $\mathrm{P}: \mathrm{B} \rightarrow \mathrm{S}^{2}$ for $\mathrm{S}_{w}$ is null-homotopic.

### 4.2. Methods of Constructing p-forms on Spheres :

i) "From constant $(p+1)$-forms on $\mathrm{R}^{n}$ ".

Let $w \in \Lambda^{p+1} \mathrm{R}^{n}$; and define $t: \mathrm{S}^{n-1} \rightarrow \Lambda^{p} \mathrm{R}^{n}$ by $t(x)=\delta_{x}(w)$ for all $x \in \mathrm{~S}^{n-1}$, where $\delta_{x}$ is the "adjoint" of the wedge-product map, $d_{x} \vdots \Lambda \mathrm{R}^{n} \rightarrow \Lambda \mathrm{R}^{n}$ given by $d_{x}(y)=x \wedge y$. Then

$$
\delta_{x} t(x)=\delta_{x} \circ \delta_{x}(w)=0 ;
$$

and thus, $t$, is a differentiable p -form on $\mathrm{S}^{n-1}$.
ii) "From constant p-forms on $\mathrm{R}^{n "}$

Let $w \in \Lambda^{p} \mathrm{R}^{n}$. Then $t(x)=\delta_{x} \circ d_{x}(w)=w-d_{x} \circ \delta_{x}(w)$ for $x \in \mathrm{~S}^{n-1}$ defines a differentiable p-form, $t$, on $\mathrm{S}^{n-1}$ which is called the "tangential component" of $w$.

Proposition. - The tangential-component of a normalized 2-form of maximal-rank on $\mathrm{R}^{2 n}$ is a 2 -form on $\mathrm{S}^{2 n-1}$ of constant rank $(2 n-2)$.

Proof. $-w=x \wedge \delta_{x}(w)+t(x)$ for all $x \in \mathrm{~S}^{n-1}$. The transformation on $\mathrm{R}^{2 n}$ given by $x \rightarrow \delta_{x}(w)$ has square equal to minus ldentity; and thus $\delta_{\delta_{x}(w)}(t(x))=0$ which implies that $t(x) \in \Lambda^{2} \mathrm{U}_{x}$ for

$$
\mathrm{U}_{x}=\left(x ; \delta_{x}(w)\right) ;
$$

and hence $\operatorname{rank}(w)=\operatorname{rank}\left(x \wedge \delta_{x}(w)\right)+\operatorname{rank} t(x)$.

Note. $-t(-x)=t(x)$; and thus, $t$, also defines a 2 -form on $\mathrm{P}^{2 n-1}$ of constant rank (2n-2).
4.3. Existence and decomposability of 2-forms of constant rank on spheres :

Proposition. -- $S^{4 n+3}$ admits a 2-form of constant rank $4 n$.

Proof. - Represent $\mathrm{S}^{4 n+3}=\mathrm{S} p(n+1) / \mathrm{S} p(n)$; and let

$$
w_{0}=e_{1} \wedge e_{2 n+1}+\cdots+e_{2 n} \wedge e_{4 n}
$$

be a "normalized" 2 -form at the distinguished point $e_{4 n+3}$. For $x \in \mathrm{~S}^{4 n+3}$, take any $u \in \mathrm{~S} p(n+1)$ such thất $u\left(e_{4 n+3}\right)=x$; and define $w(x)=\left(\Lambda^{2} u\right) w_{0}$. Since, $\mathrm{S} p(n) \subset \mathrm{U}(2 n)$ leaves $w_{0}$-invariant ; $w$ is a well defined 2-form on $S^{4 n+3}$ of constant rank $4 n$. Q.E.D.

Note. - i) $w\left(e^{i \theta} x\right)=e^{2 i \theta} w(x)$ and ii) $\delta_{\mathrm{J}(x)}(w(x))=0 \quad$ where J is multiplication by $i=\sqrt{-1}$; and thus, $w$, defines a 2 -form on $\mathrm{P}_{2 n+1}(\mathrm{C})$ (and hence on $\mathrm{P}^{4 n+3}$ ) of constant rank $4 n$.

Combining Proposition 2.2 with the Standard Theorem of [7] pp. 144 ; we obtain the following :

Statement. - The existence of a 2-form of constant rank $2 s$ on $\mathrm{S}^{n}$ implies :
i) the existence of a field of $2 s$-frames on $\mathrm{S}^{n}$ for $4 s \leqslant n$.
ii) the existence of a field of $(n-2 s)$-frames on $S^{n}$ for $4 s>n$. and using Adams' results on Vector Fields on Spheres ; we deduce :

Corollary 1. - $\mathrm{S}^{4 n+1}$ does not admit a 2-form of constant $\operatorname{rank} 2 s$ for $0<s<2 n$.

Corollary 2. - $\mathrm{S}^{2 n}$ does not admit a 2-form of constant rank $2 s$ for $0<s<n$.

It is also a consequence of Adams' results and Kirchoff's Theorem (Refer to [7] pp. 217) that $S^{2}$ and $S^{6}$ are the only even dimensional spheres which are almost-complex, i.e. admit 2 -forms of maximal rank. We can, now, summarize all these results in the following :

Theorem. - 1) The only even dimensional spheres which admit 2-forms of constant rank are $\mathrm{S}^{2}$ and $\mathrm{S}^{6}$ which admit 2-forms of maximal rank. None of these forms can be decomposed.
2) The only non-zero 2-forms of constant rank on $S^{4 n+1}$ are those of rank $4 n$, and none of these forms can be decomposed.
3) $\mathrm{S}^{4 n+3}$ admits 2 -forms of constant ranks $2,4 n, 4 n+2$. Those of constant rank 2 always decompose ; whereas those of constant rank $4 n$ and $4 n+2$ cannot be decomposed for $n \geqslant 2$. A 2-form, $w$, on $\mathrm{S}^{7}$ of constant rank 4 decomposes iff i) $\mathrm{S}_{\boldsymbol{w}}$ is a trivial bundle ; and ii) $\partial\left[w_{1}\right] \in \pi_{6} \mathrm{U}(2)$ vanishes, where $w_{1}$ is the representation of the normalization of $w$ (with respect to the canonical RiemannianMetric on $\mathrm{S}^{7}$ ) arising from any trivialization of $\mathrm{S}_{w}$ as a map

$$
w_{1}: \mathrm{S}^{7} \rightarrow \mathrm{I}_{2} ; \quad \text { and } \quad \partial: \pi_{7} \mathrm{I}_{2} \rightarrow \pi_{6} \mathrm{U}(2)
$$

is the boundary-operator of the exact homotopy sequence of the fibration $\mathrm{SO}(4) \rightarrow \mathrm{I}_{2}$.

A 2-form, w, on $\mathrm{S}^{7}$ of constant rank 6 decomposes iff i)

$$
\partial[\mathrm{P}] \in \pi_{6} \mathrm{SO}(6)
$$

vanishes; where $\mathrm{P}: \mathrm{S}^{7} \rightarrow \mathrm{~S}^{6}$ is the Gauss-Map for $\mathrm{S}_{\boldsymbol{w}}$, and

$$
\partial: \pi_{7} S^{6} \rightarrow \pi_{6} S O(6)
$$

is the boundary-operator of $\mathrm{SO}(7) \rightarrow \mathrm{S}^{6}$. ii) $\partial\left[w_{1}\right] \in \pi_{6} \mathrm{U}(3)$ vanishes; where $w_{1}: \mathrm{S}^{7} \rightarrow \mathrm{I}_{3}$ is the representation of the normalization of $w$, and $\partial: \pi_{7} \mathrm{I}_{3} \rightarrow \pi_{6} \mathrm{U}(3)$ is the boundary-operator of $\mathrm{SO}(6) \rightarrow \mathrm{I}_{3}$.

Remark. - The above theorem solves completely the existence and decomposability problem of 2 -forms of constant rank for $S^{2 n}$, $S^{4 n+1}$, and for $S^{4 n+3}$ up to $S^{15}$. The first unsolved case is the existence question of 2 -forms of constant rank 10 on $\mathrm{S}^{15}$. The next is the existence question of 2 -forms of constant rank 16 and 18 on $\mathrm{S}^{\mathbf{2 3}}$.
4.4. Existence and Decomposability of 2-forms of constant rank on

Projective Spaces :
Parts 1 and 2 and most of 3 of the preceeding Theorem go through unchanged for real-projective spaces. The only changes in Part 3 are i) 2-forms, $w$, on $\mathrm{P}^{4 n+3}$ of constant rank 2 decompose iff $c_{1}\left(\mathrm{~S}_{w}\right) \in \mathrm{H}^{2}\left(\mathrm{P}^{4 n+3} ; \mathrm{Z}\right)=\mathrm{Z}_{2}$ vanishes. ii) The discussions for 2-forms on $\mathrm{S}^{7}$ do not have their analogues for $\mathrm{P}^{7}$; since, $w$, can no longer be represented as an element of $\pi_{7} I_{2}$ or $\pi_{7} I_{3}$. A necessary condition for the decomposability of such forms is the decomposability of
the corresponding forms on $S^{7}$ (which can be determined by the previous Theorem). However, whether this is sufficient is not known.

The case of the complex projective spaces can be best summarized in the following :

Proposition. - P (C), being a complex analytic manifold, admits a 2-form of constant rank $2 n$.

The only non-zero 2 -forms on $\mathrm{P}_{2 n}(\mathrm{C})$ of constant rank are those of constant rank $4 n$ which cannot be decomposed.
$\mathrm{P}_{2 n+1}(\mathrm{C})$, admits 2 -forms of constant ranks $4 n+2$ and $4 n$ which cannot be decomposed for $n \geqslant 2$.

### 4.5. Translation-Invariant 2 -forms on Lie-Groups :

Proposition. - A Lie-Group, G, admits translation-invariant 2forms of constant rank $2 s$ for $2 s \leqslant \operatorname{dim} G$; and any translationinvariant 2 -form on G decomposes.

## Appendix

The analogous problem of decomposing a 2 -form of constant rank on a complex vector-bundle is attacked in exactly the same way ; and is reduced to the lifting-problem of the diagram :

One then investigates integer-cohomology of the homogenousspace, $\mathrm{U}(2 s) / \mathrm{S} p(s)$; and the Kernel of the map, $p^{*}$ :

$$
\mathrm{H}^{*}(\mathrm{U}(2 s) / \mathrm{S} p(s)) \rightarrow \mathrm{H}^{*}(\mathrm{U}(2 s))
$$
