# ON THE DISTRIBUTION OF INTEGRAL AND PRIME DIVISORS WITH EQUAL NORMS 

by B. Z. MOROZ (*)

This is an exposition of the material presented in my lectures given at Orsay in March 1983.

## 1.

Consider $r$ finite extensions $k_{1}, \ldots, k_{r}$ of an algebraic number field $k$, a finite extension of $\mathbf{Q}$, and fix an ideal class $\mathbf{A}_{j}$ in $k_{j}, 1 \leqslant j \leqslant r$. Let

$$
V(A)=\left\{a \mid a_{j} \in A_{j}, N_{k_{1} / k} a_{i}=\cdots=\mathbf{N}_{k_{r} / k} a_{r}\right\}
$$

be the set of $r$-tuples of divisors having equal norms. Following E. Hecke, [1], one associates to a divisor of a number field a point in Minkowski space, the real vector space corresponding to this field; we study the distribution of integrall and prime divisors in $V(A)$ regarded as points of a real manifold, in the spirit of [1]. For technical reasons we consider here only the case $k=\mathbf{Q}$ (compare [2] and the appendix to this paper).

We use the following notations: card $S$, or simply $|S|$, denotes the cardinality of a firfite set $S$. Let $L$ be an algebraic number field of degree $n$ over $\mathbf{Q}$ :
$\mathfrak{v}$ is the ring of integers of L ,
$\mathfrak{v}^{*}$ is its group of units,
I is the group of fractional divisors of $L$, $I_{0}$ is the monoid of integral divisors,
(*) Supported in part by a French Government visiting grant.
$\mathscr{P}$ is the set of prime divisors,
$S_{2}$ and $S_{1}$ are the sets of complex and real places of $L$, $S=S_{1} \cup S_{2}, \quad\left|S_{j}\right|=: r_{j}(j=1,2), \quad n=r_{1}+2 r_{2}$, $L_{w}=\left\{\begin{array}{l}\mathbf{R}, w \in S_{1} \\ \mathbf{C}, w \in S_{2}\end{array}\right.$ denotes the completion of $L$ at $w \in S$,
$\|x\|=\left\{\begin{array}{ll}|x|, & w \in S_{1} \\ |x|^{2}, & w \in S_{2}\end{array} \quad\right.$ for $\quad x \in L_{w}$.

Let us introduce the algebra $X=\prod_{w \in S} L_{w}$ of dimension $n$ over $\mathbf{R}$, refered to as Minkowski space associated with L. Let $\psi: L \rightarrow X$ be the componentwise embedding of $L$ in $X$. The group $\mathfrak{v}^{*}$ of units acts freely as a discrete group of transformations on the multiplicative group $X^{*}=\prod_{w \in S} L_{w}^{*}$ of non-zero elements of X ; let $\mathrm{Y}=\mathrm{X}^{*} / \Psi\left(\mathfrak{v}^{*}\right)$ be the group of its orbits. E. Hecke, [1], introduces «ideal numbers» (compare also, [3][6]) and defines Größencharaktere to be able to study the distribution of integral and prime divisors among the areas of Y . We recall this construction, as well as the results of [3]-[5] to be generalized here. Let $\mathbf{N}$ : $\mathrm{X} \rightarrow \mathbf{R}_{+}$and $\mathrm{N}^{-1}: \mathbf{R}_{+} \rightarrow \mathbf{X}$ denote the norm map $\mathrm{N}: x \rightarrow \prod_{w \in \mathrm{~S}}\left\|x_{w}\right\|$ and its right inverse $\mathrm{N}^{-1}: t \rightarrow\left(t^{1 / n}, \ldots, t^{1 / n}\right)$. Since N is trivial on $\psi\left(\mathfrak{p}^{*}\right)$, one obtains $\mathrm{Y}=\mathbf{R}_{+} \times \mathrm{Y}_{0}$, where

$$
\mathbf{Y}_{0}:=\mathbf{X}_{0} / \psi\left(\mathfrak{p}^{*}\right), \quad \mathbf{X}_{0}:=\{x \mid x \in \mathbf{X}, \mathbf{N}(x)=1\}
$$

Let $\hat{\mathrm{Y}}_{0}$ be the group of characters of $\mathrm{Y}_{0}$ and $\lambda \in \hat{\mathrm{Y}}_{0}$; one can regard $\lambda$ as a character of $\mathrm{X}^{*}$ trivial on $\psi\left(\mathfrak{v}^{*}\right)$ and on $\mathbf{N}^{-1} \mathbf{R}_{+}$. Thus

$$
\begin{equation*}
\lambda(x)=\prod_{w \in \mathbf{S}}\left\|x_{w}\right\|^{i t_{w}}\left(\frac{x_{w}}{\left|x_{w}\right|}\right)^{a_{w}} \tag{1}
\end{equation*}
$$

where $a_{w} \in \mathbf{Z}, t_{w} \in \mathbf{R}, x_{w}$ denotes the projection of $x$ on $\mathrm{L}_{w}$, and, moreover, $\lambda(\varepsilon x)=\lambda(x)$ for $\varepsilon \in \psi\left(\mathfrak{v}^{*}\right)$,

$$
\sum_{w \in \mathrm{~S}_{1}} t_{w}+2 \sum_{w \in \mathrm{~S}_{2}} t_{w}=0, \quad a_{w} \in\{0,1\} \quad \text { for } \quad w \in \mathrm{~S}_{1} .
$$

It follows from the Dirichlet theorem on units (compare [1], [6]) that $\mathbf{Y}=\mathbf{R}_{+} \times \mathfrak{I}_{\mathbf{L}} \times(\mathbf{Z} / 2 Z)^{r_{0}}$, where $\mathfrak{I}_{\mathrm{L}}$ is a torus of dimension $n-1$, and $\quad r_{0} \leqslant r_{1}$. Therefore, $\hat{Y}_{0} \cong Z^{n-1} \times(Z / 2 Z)^{r_{0}}$, and there exist characters $\lambda_{1}, \ldots, \lambda_{n-1}$ multiplicatively independent over $Z$ and such
that any $\lambda \in \hat{\mathrm{Y}}_{0}$ has the form

$$
\begin{equation*}
\lambda=\prod_{v=1}^{n-1} \lambda_{v}^{m_{v}} \lambda^{\prime}, \quad m_{v} \in \mathbf{Z} \tag{2}
\end{equation*}
$$

where $\quad \lambda^{\prime}(x)=\prod_{w \in \mathrm{~S}_{1}}\left(\frac{x_{w}}{\left|x_{w}\right|}\right)^{a_{w}}, \quad a_{w} \in\{0,1\}$. The $\operatorname{map} \psi$ induces an embedding

$$
\varphi: L^{*} / \mathbf{o}^{*} \rightarrow Y
$$

of the group of principal divisors $\mathrm{L}^{*} / \mathbf{v}^{*}$ of L in Y . Composing $\varphi$ with the projection of Y on $\mathbf{R}_{+} \times \mathfrak{I}_{\mathrm{L}}$ one obtains an embedding

$$
\varphi_{0}: \mathrm{L}^{*} / \mathbf{o}^{*} \rightarrow \mathbf{R}_{+} \times \mathfrak{I}_{\mathrm{L}}
$$

Since the group $\mathrm{H}:=\mathrm{I} / \mathrm{L}^{*}$ of ideal classes is finite, one can define an embedding

$$
\begin{equation*}
f: \mathbf{I} \rightarrow \mathbf{R}_{+} \times \mathfrak{I}_{\mathbf{L}} \tag{3}
\end{equation*}
$$

which coincides with $\varphi_{0}$ on $L^{*} / \mathfrak{v}^{*}$. It follows from the work cited above (see, in particular, [1] and [3]-[5]) that both integral and prime divisors are asymptotically equidistributed when identified by means of (3) with points of the real manifold $\mathbf{R}_{+} \times \mathfrak{I}_{\mathrm{L}}$. To be more precise, let us introduce a parametrisation of $\mathfrak{I}_{\mathrm{L}}$ induced by the basic characters $\lambda_{j}(x)=\exp \left(2 \pi i \varphi_{j}(x)\right), \quad 1 \leqslant j \leqslant n-1,0 \leqslant \varphi_{j}(x)<1$, and identify a point $x \in \mathfrak{I}_{L}$ with its image $\left(\lambda_{1}(x), \ldots, \lambda_{n-1}(x)\right) \in \mathrm{T}^{n-1}$, where $T$ denotes the unit circle in $\mathbf{C}^{*}$. We call a subset

$$
\tau=\left\{x \mid \lambda_{j} \leqslant \varphi_{j}(x)<\lambda_{j}+\delta_{j}, \quad 1 \leqslant j \leqslant n-1\right\}
$$

of $\mathfrak{I}_{\mathrm{L}}$ elementary whenever $0 \leqslant \lambda_{j}<\lambda_{j}+\delta_{j} \leqslant 1$. A set $\tau \subseteq \mathfrak{I}_{\mathrm{L}}$ is called smooth if there exists a constant $C(\tau)>0$ such that for every $\Delta>0$ one can find a system $t=\left\{\tau_{v}\right\}$ of elementary sets with the following properties: $\operatorname{card}(t)<\Delta^{-(n-1)}$,

$$
\tau_{v} \cap \tau_{v}=\varnothing \text { for } v \neq v^{\prime}, \quad \tau \subseteq \bigcup_{\tau_{v} \in t} \tau_{v}, \quad \operatorname{mes}\left(\bigcup_{\tau_{v} \cap \partial \tau \neq \varnothing} \tau_{v}\right)<C(\tau) \Delta,
$$

where mes is the normalized Haar measure on $\mathfrak{I}_{\mathrm{L}}$ (so that mes $\left(\mathfrak{I}_{\mathrm{L}}\right)=1$ ) and $\partial \tau$ denotes the boundary of $\tau$. The following theorem has been proved by J. P. Kubilius, [4], and, a few years later, by T. Mitsui, [5].

Theorem 1.-For any smooth set $\tau \subseteq \mathfrak{I}_{\mathrm{L}}$ and any ideal class $\mathrm{A} \in \mathrm{H}$
$\operatorname{card}\left\{\mathfrak{a} \mid \mathfrak{a} \in \mathrm{I}_{0}, \quad f(\mathfrak{a}) \in(0, x) \times \tau, \quad \mathfrak{a} \in \mathrm{A}\right\}=\frac{\omega_{\mathrm{L}} \operatorname{mes}(\tau)}{h} x+\mathbf{O}\left(x^{1-c_{1}}\right)$
$\operatorname{card}\{\mathfrak{p} \mid \mathfrak{p} \in \mathscr{P}, f(\mathfrak{p}) \in(0, x) \times \tau, \mathfrak{p} \in \mathrm{A}\}$

$$
=\frac{\operatorname{mes}(\tau)}{h} \int_{2}^{x} \frac{d x}{\log x}+\mathrm{O}\left(\exp \left(-c_{2} \sqrt{\log x}\right) x\right)
$$

where the constants $c_{1}, c_{2}>0$ depend on L , but not on $x \rightarrow \infty$, and $\omega_{\mathrm{L}}$ denotes the residue of the zeta-function of L at $s=1, h:=|\mathrm{H}|$ is the class number of L .

The characters $\mu_{j}=\lambda_{j} \circ f$ are called basic Größencharaktere; the group

$$
\hat{\mathrm{I}}=\left\{\mu \mid \mu=\chi \prod_{j=1}^{n-1} \mu_{j}^{m_{j}}, m_{j} \in \mathbf{Z}, \chi \in \hat{\mathbf{H}}\right\}
$$

where $\hat{H}$ is the group of ideal class characters, can be identified (see, e.g., [6]) with the set of unramified idele-class characters trivial on $\mathbf{R}_{+}$. The map

$$
g^{\prime}: \mathrm{I} \rightarrow \mathbf{R}_{+} \times \mathrm{T}^{n-1}
$$

given by

$$
g^{\prime}: \mathfrak{a} \mapsto\left(\mathrm{N}_{\mathrm{L} / \mathfrak{Q}} \mathfrak{a}, \mu_{1}(\mathfrak{a}), \ldots, \mu_{n-1}(\mathfrak{a})\right)
$$

is compatible with (3) under the above identification of $\mathfrak{I}_{\mathrm{L}}$ and $\mathrm{T}^{n-1}$. Theorem 1 may be viewed as a multidimensional equidistribution principle, in the spirit of the classic memoir of Hecke's, [1]. We should like to refer to [8], [9], [10] for some applications of this principle. One can improve the error term in the second formula using the method of trigonometric sums (see, [3], chapter 2, and [7]). About thirty years ago Yu. V. Linnik suggested (and communicated to his colleagues and students, [11]) that one could generalize Theorem 1 to treat the integral and prime divisors in $\mathrm{V}(\mathrm{A})$. As an example of this programme (compare [2] and references therein), we prove here the following result. Let $I_{0}^{j}, \mathscr{P}_{j}, \mathfrak{I}_{j}$ and $h_{j}$ denote the monoid of integral divisors, the set of prime divisors, the torus $\mathfrak{I}_{k_{j}}$ and the class number of $k_{j}$ respectively; let $h=\prod_{j=1}^{r} h_{j}$ and $\mathfrak{I}=\mathfrak{I}_{1} \times \cdots \times \mathfrak{I}_{r}, \quad$ moreover, let $\quad \mathscr{P}=\left\{\mathfrak{p} \mid \mathfrak{p}_{j} \in \mathscr{P}_{j}\right\} \quad$ and $\mathrm{I}_{0}=\left\{\mathfrak{a} \mid \mathfrak{a}_{j} \in \mathrm{I}_{0}^{j}\right\} \quad$ be the sets of $r$-tuples of prime and integral divisors
respectively; let $\mathrm{K}=k_{1} \ldots k_{r}$ be the composite of the fields $k_{1}, \ldots, k_{r}$, let $n_{j}$ and $\mathrm{D}_{j}$ be the degree $\left[k_{j}: \mathbf{Q}\right.$ ] and the discriminant of $k_{j}$ and $n$ be the degree $[\mathrm{K}: \mathbf{Q}]$ of K . Consider the map

$$
g_{j}: \mathrm{I}_{\mathrm{o}}^{\mathrm{j}} \rightarrow \mathfrak{I}_{j}
$$

induced by the embedding ( $3^{\prime}$ ), so that, when $\mathfrak{I}_{j}$ is identified with $\mathrm{T}^{n_{j}-1}$,

$$
g_{j}: \mathfrak{a}_{j} \mapsto\left(\mu_{j 1}\left(\mathfrak{a}_{j}\right), \ldots, \mu_{j_{j}-1}\left(\mathfrak{a}_{j}\right)\right), \quad \mathfrak{a}_{j} \in \mathbb{I}_{0}^{j},
$$

where $\left\{\mu_{j} \mid 1 \leqslant \ell \leqslant n_{j}-1\right\}$ is the set of basic Größencharaktere of $k_{j}$, $j=1, \ldots, r$, and introduce a zeta-function

$$
\begin{equation*}
\mathrm{Z}\left(k_{1}, \ldots, k_{r} ; s\right)=\sum_{m=1}^{\infty} a_{m}^{(1)} \ldots a_{m}^{(r)} m^{-s} \tag{4}
\end{equation*}
$$

where $a_{m}^{(j)}=\operatorname{card}\left\{\mathfrak{a}_{j} \mid \mathfrak{a}_{j} \in I_{o}^{(j)}, \mathbf{N}_{k_{j} / \mathfrak{o}} \mathfrak{a}_{j}=m\right\}$ is the number of integral divisors of $k_{j}$ whose norm is equal to $m$. One can show (see [12], [13]) that if $n=\prod_{j=1}^{r} n_{j}$, then

$$
\begin{equation*}
\mathrm{Z}\left(k_{1}, \ldots, k_{r} ; s\right)=\frac{\mathrm{Z}_{\mathrm{K}}(s)}{\mathrm{L}(s, \Phi)}, \tag{5}
\end{equation*}
$$

where $\mathrm{L}(s, \Phi)=\prod_{p} \Phi^{(p)}\left(p^{-s}\right)^{-1}, \Phi^{(p)}(t)$ is a rational function of $t, p$ varies over rational primes, and, moreover, $\Phi^{(p)}\left(p^{-s}\right) \neq 0, \infty$ for Re $s>\frac{1}{2}$; for almost all $p$ the function $\Phi^{(p)}(t)$ is a polynomial of degree not larger than $n-1$ and such that $\Phi^{(p)}(0)=1,\left.\frac{d}{d t} \Phi^{(p)}\right|_{t=0}=0$. In particular, the Euler product

$$
\mathrm{L}(s, \Phi)=\prod_{p} \Phi^{(p)}\left(p^{-s}\right)^{-1}
$$

converges absolutely for $\operatorname{Re} s>\frac{1}{2}$.
Theorem 2. - If $k_{j}$ is Galois over $\mathbf{Q}$ for every $j, n=\prod_{j=1}^{r} n_{j}$ and $\left(\mathrm{D}_{j}, \mathrm{D}_{\ell}\right)=1$ for $j \neq \ell \quad$ (the discriminants are pairwise coprime), then for
any smooth set $\tau \subseteq \mathfrak{I}$ one has

$$
\begin{aligned}
& \operatorname{card}\left\{\mathfrak{a}\left|\mathfrak{a} \in \mathrm{V}(\mathrm{~A}) \cap \mathrm{I}_{0},|\mathfrak{a}|<x, g(\mathfrak{a}) \in \tau\right\}=\frac{\omega_{\mathrm{K}} \operatorname{mes}(\tau)}{h \mathrm{~L}(1, \Phi)} x+\mathrm{O}\left(x^{1-c_{1}}\right),\right. \\
& \begin{aligned}
& \operatorname{card}\{\mathfrak{p}|\mathfrak{p} \in \mathrm{V}(\mathrm{~A}) \cap \mathscr{P},|\mathfrak{p}|=x, g(\mathfrak{p}) \in \tau\} \\
&= \frac{\operatorname{mes}(\tau)}{h} l i(x)+\mathrm{O}\left(x \exp \left(-c_{2} \sqrt{\log x}\right)\right)
\end{aligned}
\end{aligned}
$$

for some $c_{1}, c_{2}>0$ depending on $k_{1}, \ldots, k_{r}$, but not on $x \rightarrow \infty$, where

$$
|\mathfrak{a}|:=\left(\sum_{j=1}^{r} \mathbf{N}_{k_{j} / \mathbf{Q}} \mathfrak{a}_{j}\right) \frac{1}{r} \text { for } \mathfrak{a}=\left\{\mathfrak{a}_{1}, \ldots, \mathfrak{a}_{r} \mid \mathfrak{a}_{j} \in \mathrm{I}_{0}^{j}\right\}
$$

and

$$
l i(x):=\int_{2}^{x} \frac{d u}{\log u} ; g=\left(g_{1}, \ldots, g_{r}\right)
$$

One can view Theorem 2 as a statement about statistical independence of the fields $k_{1}, \ldots, k_{r}$. To be more precise, let

$$
\tau=\tau_{1} \times \cdots \times \tau_{r}, \quad \tau_{j} \subseteq \mathfrak{I}_{j}
$$

then (under the above assumptions) the probability to find $a \in V(A)$ with $g(a) \in \tau$ is equal to the product of the probabilities that $\mathfrak{a}_{j} \in \mathrm{~A}_{j}$ and $g_{j}\left(\mathfrak{a}_{j}\right) \in \tau_{j}, \quad j=1, \ldots, r$. Thus the condition

$$
\begin{equation*}
\mathbf{N}_{k_{1} / \mathbf{Q}} \mathfrak{a}_{1}=\cdots=\mathbf{N}_{k_{r} / \mathbf{Q}} \mathbf{a}_{r} \tag{6}
\end{equation*}
$$

affects the probability of the event:

$$
« a_{1} \in A_{1}, \ldots, a_{r} \in A_{r}, g_{1}\left(a_{1}\right) \in \tau_{1}, \ldots, g_{r}\left(a_{r}\right) \in \tau_{r} »
$$

neither for $r$-tuples of integral, nor of prime divisors. On the other hand, Theorem 2 may be regarded as an assertion on representation of integers by decomposable forms. As a special case of this theorem ( $n_{1}=\cdots=n_{r}=2$ ), one obtains the following result.

Proposition 3. - Let $f_{1}, \ldots, f_{r}$ be binary positive definite primitive quadratic forms with pairwise co-prime fundamental discriminants. Then the number of integral solutions

$$
\left(x_{1}, x_{2}, \ldots, x_{2 r-1}, x_{2 r}\right)
$$

of the system of equations

$$
f_{1}\left(x_{1}, x_{2}\right)=\cdots=f_{r}\left(x_{2 r-1}, x_{2 r}\right)
$$

subject to the condition $f_{1}\left(x_{1}, x_{2}\right) \leqslant \mathrm{N}$ is equal to

$$
A N+O\left(N^{1-c}\right)
$$

for some $\mathrm{A}>0, c>0$ independent on N .
It turns out that for two quadratic fields $\left(n_{1}=n_{2}=r=2\right)$

$$
\mathrm{L}(s, \Phi)=\mathrm{L}\left(2 s, \chi_{0}\right)
$$

where $\chi_{0}(n)=\left(\frac{D_{1} D_{2}}{n}\right)$ (see, e.g., [13], § 5). Therefore we obtain the following result.

Proposition 4. - Let $k_{j}=\mathbf{Q}\left(\sqrt{\mathrm{D}_{j}}\right), j=1,2,\left(\mathrm{D}_{1}, \mathrm{D}_{2}\right)=1$. Then
$\operatorname{card}\left\{\mathfrak{a}\left|\mathfrak{a} \in \mathrm{V}(\mathrm{A}) \cap \mathrm{I}_{0},|\mathfrak{a}|<x, g(\mathfrak{a}) \in \tau\right\}=\frac{\omega_{\mathrm{K}} \operatorname{mes}(\tau)}{h \mathrm{~L}\left(2, \chi_{0}\right)} x+\mathrm{O}\left(x^{1-c_{1}}\right)\right.$
with $c_{1}>0$ independent on $x$.
We remark finally that the O-constants depend on $\tau$ only through the «constant of smoothness» $\mathrm{C}(\tau)$, as can be readily observed from the proof of Theorem 2 given below.
2.

Further on we write $\mathrm{I}_{0}(\mathrm{~K}), \mathscr{P}(\mathrm{K}), \mathrm{H}(\mathrm{K}), \mu(\mathrm{K})$ for the monoid of the integral divisors, set of prime divisors, class group and the set of basic Größencharaktere of K . Theorem 2 will be deduced from the following four lemmas.

Lemma 1. - Let $\varphi_{1}, \varphi_{2}, \varepsilon$ satisfy the inequalities

$$
0 \leqslant \varphi_{1}-\varepsilon<\varphi_{1}<\varphi_{2}<\varphi_{2}+\varepsilon \leqslant 1
$$

There exists a real valued function $f \in \mathrm{C}^{\infty}[0,1]$ such that $0 \leqslant f(t) \leqslant 1$ for $t \in[0,1], f(t)=1$ for $t \in\left[\varphi_{1}, \varphi_{2}\right], f(t)=0$ for $t \notin\left[\varphi_{1}-\varepsilon, \varphi_{2}+\varepsilon\right]$,

$$
f^{\prime}(t) \neq 0 \text { for } \varphi_{1}-\varepsilon<t<\varphi_{1} \text { and } \varphi_{2}<t<\varphi_{2}+\varepsilon \text { : }
$$

This is a well-known lemma of elementary calculus; we choose one of such functions to be denoted by $f\left(\varphi_{1}, \varphi_{2}, \varepsilon ;\right.$.).

Let $\mathrm{C}_{j}, \mathrm{C}_{\mathrm{K}}$ be the idele class groups of $k_{j}, \mathrm{~K}$, and $\chi_{j}$ be an idele class character of $\boldsymbol{k}_{\boldsymbol{j}}$ trivial on $\mathbf{R}_{+}$; we define an idele class character

$$
\begin{equation*}
\chi:=\prod_{j=1}^{r} \chi_{j} \circ \mathbf{N}_{\mathbf{K} / k_{j}} \tag{7}
\end{equation*}
$$

in $K$, and an $L$-function

$$
\mathrm{L}\left(\chi_{1}, \ldots, \chi_{r} ; s\right):=\sum_{a \in \mathrm{~V}} \chi_{1}\left(\mathfrak{a}_{1}\right) \ldots \chi_{r}\left(\mathfrak{a}_{r}\right)|\mathfrak{a}|^{-s}
$$

where $\quad V=\left\{\mathfrak{a} \mid \mathfrak{a}_{j} \in I_{0}^{j}, N_{k_{1} / \mathbf{Q}} \mathfrak{a}_{1}=\cdots=N_{k_{r} / \mathbf{Q}} \mathfrak{a}_{r}\right\}$.
Lemma 2. - If $n=\prod_{j=1}^{r} n_{j}$, then $\mathrm{L}\left(\chi_{1}, \ldots, \chi_{r} ; s\right)=\mathrm{L}(s, \chi) \mathrm{L}(s, \Phi)^{-1}$, where $\mathrm{L}(s, \chi)=\sum_{a \in \mathrm{I}_{0}(\mathrm{~K})} \chi(\mathfrak{a}) \mathrm{N}_{\mathrm{K} / \mathrm{Q}^{2}} \mathfrak{a}^{-s}$ for $\operatorname{Re} s>1$, and $\mathrm{L}(s, \Phi)$ as defined in (5) with $\Phi^{(p)}$ depending on $\chi_{1}, \ldots, \chi_{r}$ and having the properties similar to those of the polynomials in (5).

This follows from the results cited before, [12] (or [13]).
Lemma 3. - Let $n=\prod_{j=1}^{r} n_{j}$, then
(8) $\sum_{a \in V,|a|<x} \chi_{1}\left(a_{1}\right) \ldots \chi_{r}\left(a_{r}\right)=g(\chi) \frac{\omega_{K} x}{\mathrm{~L}(1, \Phi)}+\mathrm{O}\left(a(\chi)^{\frac{3 n+1}{2}} x^{1-c_{1}}\right)$,
(9) $\sum_{a \in V \cap \text { P, }|a|<x} \chi_{1}\left(\mathfrak{a}_{1}\right) \ldots \chi_{r}\left(a_{r}\right)$

$$
=g(\chi) \int_{2}^{x} \frac{d x}{\log x}+\mathrm{O}\left(x \exp \left(-c_{2} \frac{\log x}{\log a(\chi)+\sqrt{\log x}}\right)\right)
$$

where $c_{1}, c_{2}>0, g(\chi)=\left\{\begin{array}{l}0, \chi \neq 1 \\ 1, \chi=1\end{array}\right.$, the 0 -constants and $c_{1}, c_{2}$ depend on $k_{1}, \ldots, k_{r}$, but not on $\chi_{1}, \ldots, \chi_{r}$ unless $\chi^{2}=1$, nor on $x$; $\sum_{w \in S}\left(\left|a_{w}\right|+\left|b_{w}\right|\right)=: a(\chi)$, when $\chi$ is given by

$$
\begin{equation*}
\chi(\alpha)=\prod_{w \in S}\left(\frac{\alpha_{w}}{\left|\alpha_{w}\right|}\right)^{a_{w}} \cdot\left|\alpha_{w}\right|^{i b_{w}} \tag{10}
\end{equation*}
$$

for $\alpha \equiv 1(\bmod \mathfrak{f}(\chi)), \alpha \in \mathbf{K}^{*}, a_{w} \in \mathbf{Z}, b_{w} \in \mathbf{R} ; \alpha_{w}$ denotes the image of $\alpha$ in $K_{w}$ for $w \in S$ and $f(\chi)$ is the conductor of $\chi$.

Proof. - To prove (9) one remarks (see, e.g., [14], Lemma 1) that for any $\mathfrak{a} \in \mathrm{V} \cap \mathscr{P}$ satisfying the condition $«|\mathfrak{a}|=q$ is a rational prime» there exists one and only one prime $\mathfrak{p} \in \mathscr{P}(\mathrm{K})$ such that $\mathrm{N}_{\mathbf{K} / \mathfrak{k}_{j}} \mathfrak{p}=\mathfrak{a}_{j}$. Therefore,

$$
\begin{aligned}
\sum_{a \in \mathrm{~V} \cap \mathcal{G},|a|<x} \chi_{1}\left(\mathfrak{a}_{1}\right) \ldots \chi_{r}\left(\mathfrak{a}_{r}\right) & =\sum_{\mathfrak{a} \in \mathrm{V} \cap \mathscr{S}_{,|a|=q}^{q<x}} \chi_{1}\left(\mathfrak{a}_{1}\right) \ldots \chi_{r}\left(\mathfrak{a}_{r}\right)+\mathrm{O}\left(x^{1 / 2}\right) \\
& =\sum_{\mathfrak{p} \in \mathcal{P}(\mathbf{K}), N_{K} / \mathcal{Q}^{\mathfrak{p}<x}} \chi(\mathfrak{p})+\mathrm{O}\left(x^{1 / 2}\right)
\end{aligned}
$$

and (9) follows from estimates obtained in the work cited above (see [4], ch. I, §8, lemma 4, or [5], § 2, lemma 6) (*). By a standard argument one obtains (see, e.g., [15], lemma 3.12)

$$
\begin{aligned}
\mathrm{A}(x):=\sum_{a \in \mathrm{~V},|a|<x} \chi_{1}\left(\mathfrak{a}_{1}\right) \ldots & \chi_{r}\left(a_{r}\right) \\
& =\frac{1}{2 \pi i} \int_{c-i \mathbf{T}}^{c+\pi} \frac{\chi^{s}}{s} \mathrm{~L}\left(\chi_{1}, \ldots, \chi_{r} ; s\right) d s+\mathrm{O}_{\varepsilon}\left(\frac{x^{1+\varepsilon}}{\mathrm{T}}\right),
\end{aligned}
$$

where $c=1+(\log x)^{-1}, \mathrm{~T}>0$. It follows from lemma 2 that

$$
\begin{aligned}
\mathrm{A}(x)= & \frac{1}{2 \pi i} \int_{1 / 2+\varepsilon-i \mathrm{~T}}^{1 / 2+\varepsilon+i \mathrm{~T}} \frac{x^{s}}{s} \mathrm{~L}(s, \chi) \mathrm{L}(s, \Phi)^{-1} d s+g(\chi) \frac{\omega_{\mathrm{K}} x}{\mathrm{~L}(1, \Phi)} \\
& +\mathrm{O}_{\varepsilon}\left(\frac{x^{1+\varepsilon}}{\mathrm{T}}\right)+\mathrm{O}_{\varepsilon}\left(\int_{1 / 2+\varepsilon}^{c}(|\mathrm{~L}(\sigma+i \mathrm{~T}, \chi)|+|\mathrm{L}(\sigma-i t, \chi)|) \frac{x^{\sigma}}{\mathrm{T}} d \sigma\right)
\end{aligned}
$$

because $\mathrm{L}(s, \Phi)^{-1}=\mathrm{O}_{\varepsilon}(1)$ for $\operatorname{Re} s>\frac{1}{2}+\varepsilon$.
(*) Alternatively one can deduce (9) from lemma 2.

By a Phragmén-Lindelöf type of argument (compare, [6], pp. 92-93 and [5], pp. 14-15) one deduces from the functional equation for $L(s, \chi)$ and Stirling's formula for the $\Gamma$-function an estimate

$$
\begin{equation*}
\mathrm{L}(\sigma+i t, \chi)=\mathrm{O}_{\varepsilon}\left((1+|t|)^{\frac{3 n}{2}(1-\sigma+\varepsilon)} a(\chi)^{\frac{3 n}{2}+\varepsilon}\right) \tag{11}
\end{equation*}
$$

in the region $0 \leqslant \sigma \leqslant c$. Substitution of (11) into the estimate for $A(x)$ we have just written out leads to (8).

Lemma 4. - Let $k_{j}$ be Galois over Q for each $j, \quad n=\prod_{j=1}^{r} n_{j}$, $\left(\mathrm{D}_{j}, \mathrm{D}_{\ell}\right)=1$ for $j \neq \ell, \chi=1$, and $\chi_{j}$ be unramified for each $j$. Then $\chi_{j}=1$ for every $j$.

Proof. - Let us assume first that $\chi_{j}$ is of finite order for every $j$; then, being unramified, it is an ideal class character. One can deduce from class field theory, [17], that (under the above conditions)

$$
\left\{\left(\mathbf{N}_{K / k} 1 \mathbf{A}, \ldots, \mathbf{N}_{\mathbf{K} / k_{r}} \mathbf{A}\right) \mid \mathbf{A} \in \mathbf{H}_{\mathrm{K}}\right\}=\mathbf{H}_{1} \times \cdots \times \mathrm{H}_{r}
$$

where $H_{j}$ is the ideal class group of $k_{j}$; in particular, for any $A_{j} \in H_{j}$ there exists $\mathrm{A} \in \mathrm{H}_{\mathrm{K}}$ such that $\mathbf{N}_{\mathbf{K} / \mathbf{k}_{j}} \mathbf{A}=\mathbf{A}_{j} ; \mathbf{N}_{\mathbf{K} / \mathrm{k}_{\ell}} \mathbf{A}=1$ for $\ell \neq j$. If $\chi=1$, then

$$
1=\prod_{\ell=1}^{r}\left(\chi_{\ell} \circ \mathrm{N}_{\mathbf{K} / k_{\ell}}\right)(\mathrm{A})=\chi_{j}\left(\mathrm{~A}_{j}\right)
$$

and we see that $\chi_{j}=1$. Assuming $\chi=1$ we deduce now that $\chi_{j}$ is of finite order for any $j$. Let $G_{j}$ be the Galois group of $k_{j}$ and $G$ be the Galois group of $K$; since $n=\prod_{j=1}^{r} n_{j}$, we have $G \cong G_{1} \times \cdots \times G_{r}$. The character

$$
\left(\chi_{j} \circ \mathbf{N}_{\mathrm{K} / \mathrm{k}_{j}}\right)^{-1}=\prod_{\ell \neq j} \chi_{\ell} \circ \mathbf{N}_{\mathrm{K} / \mathrm{k}_{\ell}}
$$

is, therefore, $\mathrm{G}_{j}$-invariant; since $\left[\mathrm{C}_{j}: \mathrm{N}_{\mathrm{K} / \mathrm{k}_{j}} \mathrm{C}_{\mathrm{K}}\right]=d_{j}$ is finite, we see that $\chi_{j}^{d_{j}}$ is $G_{j}$-invariant. Take $\mathfrak{p} \in \mathscr{P}_{j}$; since $\chi_{j}^{d_{j}}(\mathfrak{p})=\chi_{j}^{d_{j}}\left(\mathfrak{p}^{\gamma}\right)$ for $\gamma \in \mathrm{G}_{j}$, we see that $\left(\chi_{j}(\mathfrak{p})\right)^{n_{j} d_{j}}=\left(\chi_{j}(p)\right)^{f_{j}}$, where $\mathbf{N}_{k_{j} / \mathbf{Q}} \mathfrak{p}=p^{f_{j}}$. But any idèle class character in $\mathbf{Q}$ is of finite order, and it follows, therefore, that $\chi_{j}^{\ell}=1$ for some $\ell$.

## 3.

Theorem 2 can be deduced from lemma 3 and lemma 4 on purely formal lines. It is an easy consequence of these lemmas and the following form of the Weyl's equidistribution principle (compare [1], p. 37, and [18], Satz 3). To state it we appeal to lemma 1 and write

$$
f\left(\varphi_{1}, \varphi_{2}, \varepsilon ; t\right)=\sum_{n=-\infty}^{\infty} c_{n} \exp (2 \pi \mathrm{int})
$$

so that

$$
\begin{equation*}
c_{0}=\left(\varphi_{2}-\varphi_{1}\right)+\mathrm{O}(\varepsilon), \quad c_{n}=\mathrm{O}\left(\frac{1}{|n|^{k} \varepsilon^{k-1}}\right) \tag{12}
\end{equation*}
$$

for any fixed integral $k \geqslant 1$.
Proposition 5. - Let

$$
\mathfrak{I}=\left\{\exp \left(2 \pi i \varphi_{1}\right), \ldots, \exp \left(2 \pi i \varphi_{m}\right) \mid 0 \leqslant \varphi_{j}<1, j=1, \ldots, m\right\}
$$

be a torus of dimension $m, \tau$ be a smooth subset of $\mathfrak{T}, G$ be a finite Abelian group with the group of characters G and

$$
\mathfrak{I}=\left\{\lambda_{1}^{\ell_{1}} \ldots \lambda_{m}^{\ell_{m}} \mid \ell_{j} \in \mathbf{Z}, \lambda_{j}: x \mapsto x_{j}\right\}
$$

be the group of characters of $\mathfrak{I}, x=\left(\ldots, \exp \left(2 \pi i \varphi_{j}\right)=x_{j}, \ldots\right) \in \mathfrak{I}$. Consider a set W and three maps :

$$
g_{1}: \mathrm{W} \rightarrow \mathfrak{I}, \quad g_{2}: \mathrm{W} \rightarrow \mathrm{G}, \quad \mathrm{~N}: \mathrm{W} \rightarrow \mathbf{R}_{+}
$$

we denote by $\hat{\mathrm{W}}$ the set of functions on W defined by

$$
\hat{\mathbb{W}}=\left\{\mu \mid \mu(\mathfrak{a})=\left(\lambda \circ g_{1}\right)(\mathfrak{a})\left(\lambda^{\prime} \circ g_{2}\right)(\mathfrak{a}), \lambda \in \mathfrak{I}, \lambda^{\prime} \in \hat{G}\right\}
$$

where $\mathfrak{a}$ varies over the elements of W . If

$$
\begin{equation*}
\sum_{\mathrm{N} a<x} \chi(\mathfrak{a})=g(\chi) \mathrm{A}(x)+\mathrm{O}\left(x \mathrm{~B}(x, a(\chi))^{-1}\right) \tag{13}
\end{equation*}
$$

for $\chi \in \hat{W}$, where

$$
g(\chi)=\left\{\begin{array}{l}
1, \lambda=1 \text { and } \lambda^{\prime}=1 \\
0, \text { otherwise }
\end{array} ; \quad \mathbf{A}(x)=\mathrm{O}(x), \quad a(\chi):=\sum_{j=1}^{m}\left|\ell_{j}\right|\right.
$$

for

$$
\chi=\left(\lambda \circ g_{1}\right)\left(\lambda^{\prime} \circ g_{2}\right), \quad \lambda^{\prime} \in \hat{G}, \quad \lambda=\prod_{j=1}^{m} \lambda_{j}^{j_{j}},
$$

then for any smooth subset $\tau$ of $\mathfrak{I}$ and any $\gamma \in \mathrm{G}$ we have
(14) $\operatorname{card}\left\{\mathfrak{a} \mid \mathfrak{a} \in \mathrm{W}, g_{2}(\mathfrak{a})=\gamma, g_{1}(\mathfrak{a}) \in \tau, \mathrm{Na}<x\right\}$

$$
=\mathrm{A}(x) \frac{\operatorname{mes}(\tau)}{|\mathrm{G}|}+\mathrm{O}\left(\frac{x}{b(x)}\right)
$$

where $b(x)$ can be chosen to be equal to $b_{1}(x)^{v}$ with $v>0$, and $b_{1}(x)$ is determined by

$$
\sum_{\ell_{1}, \ldots, \ell_{m}=-\infty}^{\infty} \frac{1}{\mathrm{~B}(x, a(\ell))} \alpha(\ell)=b_{1}(x)^{-1}, \quad a(\ell)=\sum_{j=1}^{m}\left|\ell_{j}\right|
$$

with $\alpha(\ell)=\prod_{j=1}^{m} \alpha_{j}\left(\ell_{j}\right), \alpha_{j}\left(\ell_{j}\right)=\left\{\begin{array}{l}1, \ell_{j}=0 \\ \ell_{j}^{-k}, \ell_{j} \neq 0\end{array}, k\right.$ can be chosen to be any positive integer.

Proof. - We deduce (14) from (13) for rectangular $\tau$ by means of lemma 1 and then prove (14) for any smooth $\tau \subseteq \mathfrak{T}$. Let

$$
\tau=\left\{\varphi \mid \psi_{j} \leqslant \varphi_{j}<\psi_{j}+\delta_{j}, j=1, \ldots, m\right\}
$$

Choose $\varepsilon>0$ and set (using notations of lemma 1)

$$
\begin{gathered}
f_{j}^{+}\left(\varphi_{j}\right)=f\left(\psi_{j}, \psi_{j}+\delta_{j}, \varepsilon ; \varphi_{j}\right) \\
f_{j}^{-}\left(\varphi_{j}\right)=f\left(\psi_{j}-\varepsilon, \psi_{j}-\varepsilon+\delta_{j}, \varepsilon ; \varphi_{j}\right) \\
\mathrm{F}^{ \pm}=\prod_{j=1}^{m} f_{j}^{ \pm}
\end{gathered}
$$

Let $\mathscr{N}$ denote the left hand side in (14). Obviously,

$$
\sum_{\substack{N a<x \\ g_{2}(a)=\gamma}} F^{-}\left(g_{1}(a)\right) \leqslant \mathscr{N} \leqslant \sum_{\substack{N a<x \\ g_{2}(a)=\gamma}} F^{+}\left(g_{1}(\mathfrak{a})\right) .
$$

On the other hand,

$$
\begin{equation*}
\sum_{\substack{N a<x \\ g_{2}(a)=\gamma}} F^{ \pm}\left(g_{1}(\mathfrak{a})\right)=\frac{1}{|G|} \sum_{N a<x} \sum_{x \in \mathrm{G}} \overline{\chi(\gamma)} \mathrm{F}^{ \pm}\left(g_{1}(\mathfrak{a})\right) \chi\left(g_{2}(\mathfrak{a})\right) . \tag{16}
\end{equation*}
$$

Write $f_{j}^{ \pm}(t)=\sum_{n=-\infty}^{\infty} c_{n j}^{ \pm} \exp (2 \pi \mathrm{int})$ and denote the left hand side in (16) by $\mathscr{N}^{ \pm}$. It follows from (16) that

$$
\mathcal{N}^{ \pm}=\sum_{\mu \in \mathbb{W}} c^{ \pm}(\mu) \sum_{N a<x} \mu(\mathfrak{a})
$$

where

$$
c^{ \pm}(\mu)=\frac{1}{|G|} \bar{\chi}(\gamma) \prod_{j=1}^{m} c_{\ell_{j} j}^{ \pm} \quad \text { for } \quad \mu=\left(\left(\lambda_{1}^{\ell_{1}} \ldots \lambda_{m}^{\ell_{m}}\right) \circ g_{1}\right)\left(\chi \circ g_{2}\right)
$$

Équation (13) and estimate (12) give

$$
\begin{aligned}
\mathscr{N}^{ \pm} & =\frac{1}{|\mathrm{G}|}\left(\prod_{j=1}^{m} \delta_{j}\right) \mathrm{A}(x)+\mathrm{O}(x \varepsilon)+\sum_{\substack{\mu \in \mathbb{W} \\
\mu \neq 1}}\left|c^{ \pm}(\mu)\right|\left|\sum_{\mathrm{N} a<x} \mu(\mathfrak{a})\right| \\
& =\mathrm{A}(x) \frac{\operatorname{mes}(\tau)}{|\mathrm{G}|}+\mathrm{O}(x \varepsilon)+\mathrm{O}\left(\sum_{\mu \in \mathbb{W}}\left|c^{ \pm}(\mu)\right| \mathrm{B}(x, a(\mu))^{-1} x\right) .
\end{aligned}
$$

Thus

$$
\mathscr{N}^{ \pm}=\mathrm{A}(x) \frac{\operatorname{mes}(\tau)}{|\mathrm{G}|}+\mathrm{O}(x \varepsilon)+\mathrm{O}\left(\varepsilon^{-k m} x b_{1}(x)^{-1}\right)
$$

By choosing $\varepsilon^{k m+1}=b_{1}(x)^{-1}$ one obtains (14) with $b(x)=b_{1}(x)^{1 / k m+1}$. Now let $\tau \subseteq \mathfrak{I}$ be a smooth set and $t=\left\{\tau_{v}\right\}$ a system of elementary sets with the properties

$$
\begin{aligned}
\operatorname{card}(t)<\Delta^{-m}, & \tau_{v} \cap \tau_{v^{\prime}}=\varnothing \quad \text { for } \quad v \neq v^{\prime} \\
\tau & \subseteq \bigcup_{\tau_{v} \in t} \tau_{v},
\end{aligned} \quad \operatorname{mes}\left(\bigcup_{\tau_{v} \cap \tau \neq \varnothing} \tau_{v}\right)<C(\tau) . \Delta, ~ l
$$

for some $\Delta>0$. Applying (14) to every $\tau_{v} \in t$ one obtains

$$
\mathscr{N}=\mathrm{A}(x) \frac{\operatorname{mes}(\tau)}{|\mathrm{G}|}+\mathrm{O}(\mathrm{C}(\tau) \Delta x)+\mathrm{O}\left(\frac{x}{\Delta^{m} b(x)}\right)
$$

and it is enough to choose $\Delta^{m+1}=\frac{1}{b(x)}$ to finish the proof.

To deduce Theorem 2 from Proposition 5 we take $\mathrm{G}=\mathrm{H}_{1} \times \cdots \times \mathrm{H}_{r}$, where $\mathrm{H}_{j}$ denotes the ideal class group of $k_{j}$, and define W to be either $\mathrm{V}(\mathrm{A}) \cap \mathrm{I}_{0}$, or $\mathrm{V}(\mathrm{A}) \cap \mathscr{P}$. By lemma 3, one can take

$$
\mathrm{A}(x)=\frac{\omega_{\mathrm{K}}}{\mathrm{~L}(1, \Phi)} x, \quad \mathrm{~B}(x, a(\chi))=\frac{x^{c_{1}}}{a(\chi)^{\frac{3 n+1}{2}}}
$$

in the former case, and

$$
\mathbf{A}(x)=\int_{2}^{x} \frac{d x}{\log x}, \quad \mathbf{B}(x, a(x))=\exp \left(\frac{c_{2} \log x}{\log a(\chi)+\sqrt{\log x}}\right)
$$

in the latter case. Lemma 4 assures that $g(\chi)=0$ for a non-trivial character $\left(\chi_{1}, \ldots, \chi_{r}\right)$ of $H$; it can be checked easily that $a(\chi) \leqslant c_{3} \sum_{j=1}^{r} a\left(\chi_{j}\right)$ for some constant $c_{3}$ depending only on the fields $k_{1}, \ldots, k_{r}$, and that in both cases $b(x)$ has the required form to assure the right error terms in theorem 2.

## 4.

The condition $\left(\mathrm{D}_{j}, \mathrm{D}_{\ell}\right)=1$ for $j \neq \ell$ in theorem 2 and in lemma 4 can be replaced by a weaker one : for every rational prime $p$ one has $\left(e_{j}(p), e_{i}(p)\right)=1$ for $j \neq i$, where $e_{j}(p)$ denotes the ramification degree of $p$ in $k_{j}$ (compare [17]). Following the interpretation given to the scalar product of L-functions in [19] one may try to interpret theorem 2 as a statement about distribution of integral points on algebraic tori. Finally we should like to refer to [20]-[24], where the problem discussed here or similar questions were studied.

Acknowledgement. - We are grateful to Professor P. Deligne and Professor M. Gromov for several conversations related to this work, to Dr. R. Sczech for the reference [6], and to the referee for numerous remarks and comments.

## Appendix.

Following [2] we discuss here the general situation making no a priori assumptions on $k_{j}, \quad 1 \leqslant j \leqslant r$, and $k$. As before, $K$ denotes the
composite field of $k_{1}, \ldots, k_{r}$. Given any idele-class character $\chi_{j}: C_{j} \rightarrow C^{*}$ normalized by the conditions $\chi_{j} \circ \mathrm{~N}^{-1}=1$ and $\left|\chi_{j}(\alpha)\right|=1$, put

$$
b_{n}\left(\chi_{j}\right)=\sum_{N_{k_{j} / k^{a}=n}} \chi_{j}(\mathfrak{a})
$$

and define

$$
\mathrm{L}\left(s ; \chi_{1}, \ldots, \chi_{r}\right)=\sum_{\mathrm{n}} b_{\mathrm{n}}\left(\chi_{1}\right) \ldots b_{\mathrm{n}}\left(\chi_{\mathrm{r}}\right)|\mathfrak{n}|^{-s}
$$

where $n, a$ vary over integral divisors of $k, k_{j}$. It follows then from the results cited above (see [12], [13]) that

$$
\begin{equation*}
\mathrm{L}\left(s ; \chi_{1}, \ldots, \chi_{r}\right)=\prod_{j=1}^{v} \mathrm{~L}\left(s, \psi_{j}\right) \mathrm{L}(s, \Phi)^{-1} \tag{A.0}
\end{equation*}
$$

where $L\left(s, \psi_{j}\right)$ are Hecke L-functions,

$$
\begin{equation*}
\mathrm{L}(s, \Phi)=\prod_{p} \Phi^{(p)}\left(|p|^{-s}\right)^{-1} \tag{A.1}
\end{equation*}
$$

$\Phi^{(p)}(t)$ is a rational function such that $\Phi^{(p)}(t)=1+t^{2} g^{(p)}(t), \quad g^{(p)} \in \mathbf{C}[t]$ for almost all $p$ (here $p$ varies over the prime divisors of $k$ ). Moreover, both $\psi_{1}, \ldots, \psi_{v}$ and $\Phi^{(p)}$ are exactly computable as soon as $\chi_{1}, \ldots, \chi_{r}$ are given. In particular, the product (A.1) converges absolutely for $\operatorname{Re} s>\frac{1}{2}$ and

$$
\mathrm{L}(s, \Phi) \neq 0, \infty
$$

in this half-plane. If $k_{1}, \ldots, k_{r}$ are linearly disjoint over $k$, then $v=1$ and $\psi_{1}=\prod_{j=1}^{r} \chi_{j} \circ \mathrm{~N}_{\mathrm{K} / k_{j}}$ is an idele-class character in K ; if $r=2$ and $k_{1}, k_{2}$ are quadratic extensions of $k$ with co-prime discriminants, then $\mathrm{L}(s, \Phi)=\mathrm{L}\left(2 s, \chi_{0}\right)$ for some idele class character $\chi_{0}$ of $k$ (depending on $\chi_{1}, \chi_{2}$ ). We now apply these results to obtain estimates for the sums

$$
\begin{aligned}
S & =\sum_{\substack{a \in v_{0} \\
|a|<x}} \chi_{1}\left(\mathfrak{a}_{1}\right) \ldots \chi_{r}\left(a_{r}\right), \\
S_{p r} & =\sum_{\substack{p \in v_{p r} \\
|\mathfrak{p}|<x}} \chi_{1}\left(p_{1}\right) \ldots \chi_{r}\left(\mathfrak{p}_{r}\right),
\end{aligned}
$$

where $\mathrm{V}_{0}=\left\{\mathfrak{a} \mid \mathbf{N}_{k_{1} / k} a_{1}=\cdots=\mathbf{N}_{k_{r} / k} a_{r}, a_{j} \in I_{0}^{j}\right\}$,

$$
\mathbf{V}_{p r}=\left\{\mathfrak{p} \mid \mathfrak{p} \in \mathbf{V}_{0}, \mathfrak{p}_{j} \in \mathscr{P}\right\} .
$$

The implied constants in $O$-symbols depend on $\chi_{1}, \ldots, \chi_{r}$; this dependence can be expressed in terms of $a\left(\chi_{1}\right), \ldots, a\left(\chi_{r}\right)$ but we shall not do it here. Let $v_{0}$ be the number of trivial $\psi_{j}$ :

$$
v_{0}=\left|\left\{j \mid \psi_{j}=1\right\}\right|,
$$

then

$$
\begin{equation*}
\mathrm{S}=\sum_{k=1}^{v_{0}}(\log x)^{k-1} c_{k} x+\mathbf{O}\left(x^{1-\gamma}\right) \tag{A.2}
\end{equation*}
$$

$$
S_{p r}=v_{0} \int_{2}^{x} \frac{d x}{\log x}+O\left(x \exp \left(-\gamma^{\prime} \sqrt{\log x}\right)\right)
$$

for some exactly computable constants $c_{1}, \ldots, c_{v_{0}}$ and $\gamma>0, \gamma^{\prime}>0$.
The estimates (A.2) and (A.3) follow from the properties of the L functions (A.0) and (A.1) along the same lines as the corresponding estimates in the text.
